Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

doi: 10.55453/rjmm.2022.125.3.16
The article was received on December 28, 2021, and accepted for publishing on March 12, 2022.

Gut microbiota and obesity

Florentina Ioniță-Radu[1], Carmen A. Sirbu[2], Any Docu-Axelerad[3], Ion Ștefan[4]

Abstract: *Worldwide, adults and childhood obesity are increasing alarmingly, being a major health problem. Obesity is correlated with an increased incidence of various systemic diseases including cancer, heart diseases, and diabetes mellitus type 2. Risk factors for obesity are dysbiosis, genetic, socioeconomic, behavioural and environmental. The gut microbiota has beneficial effects on human health, like host immune system stimulation, being influenced by pH, or nutrient intake. Studies performed on humans and animal models reported differences regarding microbiota at lean and obese individuals. The consumption of probiotics and prebiotics may balance the microbiota with positive effects in obesity. The main aim of this review is to reveal the interaction between dysbiosis and obesity.*

Keywords: *microbiota, diabetes, obesity, health problem, cancer, immune system*

INTRODUCTION

It is well known that obesity among children has long become a health problem at least among developed countries [1,2]. In the USA, childhood obesity involves children between 5 to 14 years, who started kindergarten overweight [3]. Obesity reflects the lifestyle of ‘‘developed’’ countries and reached epidemic proportions [4-6]. Compared to 1990 the incidence of obesity has increased by 1/3 in adults and almost double in children [7]. In 2017, UNICEF concluded in the case of children that "there has been no progress to stem the rate of overweight in more than 15 years" [8]. The main and the most common risk factors involved in obesity development are physical inactivity, high fat diet, sugar excessive intake and alcohol consumption [9-12].

Obesity is strongly correlated with an increased incidence of several systemic diseases, such as cardiovascular diseases, type 2 diabetes, and cancer [13-17]. Moreover, obesity can be defined as a complex and multifactorial disease. Over the past few years, gut microbiota plays an important role in obesity pathology [13,18]. Moreover, dysbiosis is implicated not only in intestinal diseases but also in autoimmune diseases, obesity-related diseases and even mental disorders [19].

THE GUT MICROBIOTA DYSBIOSIS

The gut microbiota represents trillions of microbial cells, which has the highest density in the intestinal compartment. Archaea, Bacteria, Eukarya, and viruses represent the gut microbiota family, which can establish complex trophic relationships with each other's and to their human host, leading from symbiosis to parasitism. The gastrointestinal microbiota may be affected by pH, oxygen levels, redox status, nutrient availability, water activity, and temperature [20]. Bacteroidetes and Firmicutes can be detected from healthy human faecal samples with the help of 16 S rRNA-targeted molecular analyses [21].

It is estimated that for every human cell, 10 micro-organismal cells colonise the whole surface of the human body. The gastrointestinal tract has a higher concentration

of microorganisms, composed mostly of bacteria [22]. Therefore, the gut microbiota is a complex ecosystem that deeply affects the host health and can be modulated by environmental stimuli and genetic factors [23]. Currently, the ratio between human cells to bacteria should be closer to 1:1 (3.0x1013 to 3.8 x1013). Thus, this radio may be influenced by genetic and environmental factors. The gut microbiota has beneficial effects on human health such as host immune system stimulation, extra energy extraction, and host protection against pathogens [24]. Moreover, gut microbiota development starts with birth and is influenced by the host genome, nutrition, and lifestyle. Several factors such as pH, nutrient intake alteration (carbohydrates, proteins, and fats) perturb the microbiota composition [25]. Firstly, the gut microbiota is involved in the breakdown of substrates with resistant starch and dietary fibres, that are incompletely hydrolysed by the host enzyme at the small intestine level [25].

The fermentation products that result from the fibre breakdown are the short fatty acids such as acetate, propionate, and butyrate, which are additional sources of body energy. Therefore, thus acids can be used by the human body [25]. The propionate is taken up by the liver as a precursor for lipogenesis, gluconeogenesis, protein synthesis, acetate is used as a precursor for cholesterol synthesis, while butyrate is used as an energy source by the colonic epithelial cells [25]. The immunologist Elie Metchnikoff was the first who reported a causative link between microbes and human disorders, with the implication of compounds that result from microbial intestinal putrefaction. His research was the first to report the beneficial effects of consuming fermented food to avoid intestinal protein putrefaction in humans [8]. The axis, microbiota-gut-brain is a bidirectional axis involved in the regulation of body weight by balancing appetite, storage, and energy expenditure [26].

Taken together, the gut microbiota regulates, food digestion, nutrient uptake and metabolism, vitamins and bile acids synthesis, innate and mucosal modulation, layer development, epithelial growth, and host gene expression [27]. In humans, between obese and leans persons have been reported differences regarding the microbiota composition, functional genes, and metabolic activities [28]. Oxidative stress-induced by obesity is correlated with lipid peroxidation, DNA damage and decreased levels of antioxidants (enzymatic and non-enzymatic) [2,10-12].

Nowadays, the implication of intestinal microbiota in the progression and, prevention of metabolic dysfunction is more relevant [29]. Some bacteria may facilitate lipogenesis. Therefore, the gut microbiota of obese individuals has several genes that may be depleted or enriched. The genes related to vitamin, cofactor and nucleotide metabolism are usually depleted [21]. More than that, intestinal microbiota can regulate adipose tissue metabolism, homoeostasis, energy balance, appetite, and food uptake, playing a crucial role in obesity [30]. In obese-experimental models performed, some gut microbial strains may inhibit or attenuate the immune response related to chronic inflammation. These results suggest that microbiota plays a dual role, protective or pathogenic [31]. Targeting the gut microbiota using prebiotics, probiotics, and drugs (berberine and metformin) will have a beneficial effect on human health [32].

The immunomodulatory properties of gut microbiota have been observed especially in obese conditions. Therefore, this category of patients is characterized by an altered microbiota or microbial dysbiosis. Obese patients extract more energy from the diet compared with lean individuals leading to excessive energy stores. In obese or diabetic type 2 patients, an enrichment of the pro-inflammatory bacteria (Escherichia coli) and a decrease of anti-inflammatory bacteria (Fecalibacterium prausnitzii) had been reported. These findings suggest that these bacteria represent a source of inflammation-associated metabolic diseases [33]. Moreover, the fermentation products of gut microbiota influence the fatty acid oxidation process, fasting, bile acid production, satiety, lipogenesis, and even innate immunity [34].

A study conducted on C57BL/6 mice, which are genetically protected against obesity after consuming a diet rich in fat and carbohydrates, where colonise with obese mice microbiota. The research group reported a significant increase in body fat and insulin resistance development in C57BL/6 mice [34,35].

Gut microbiota dysbiosis is correlated with proinflammatory cytokines release, and further with increased risk of obesity. All the obesity-related factors will lead to the development of diabetes mellitus type 2 [36], liver disease [37-40], colon cancer [14,41] and even neurological pathologies (Parkinson’s disease, autism) [42]. Some studies reported that human gut microbiota may be affected by sex, so mean have lower microbial diversity the women. Regarding this aspect, women have a lower proportion of Bacteroidetes and increased levels of Akkermansia muciniphila. Instead in the case of men, Ruminococcaceae, Faecalibacterium, and Alistipes are the species detected to be higher, while Bacteroides has a decreased proportion and they do not have Prevotella [43]. The diets used for weight loss which involves high protein intake and decrease consumption of carbohydrates perturbates the microbiota. When these strategies are applied, protein fermentation by gut microbiota take place and metabolic products have released that lead to colon inflammation. Alteration regarding the proportion of Bacteroidetes and Firmicutes may conduce to obesity development [44,45].

PREBIOTICS AND PROBIOTICS IN DIGESTIVE HEALTH

Thus, probiotic supplement consumption may regulate the gut microbiota, improving the prognosis for diabetic patients [44]. Our diet habits play an important role in gut microbiota composition. Differences between intestinal microbiota among individuals fed with Western diet and those fed with a diet rich in fibres had been observed. Additionally, a diet rich in fat can promote the development of pro-inflammatory gut microbiota, leading to increased intestinal permeability and higher levels of lipopolysaccharides [46]. When we eat more high-fat and little fibres aberrant metabolites are produced, leading to the loss of tight junction integrity. This loss of integrity allows the metabolites such as lipopolysaccharides, trimethylamine to enter the circulation and to contribute to liver and adipose tissue chronic inflammation development [42]. Therefore, the relationship between gut microbiota dysbiosis and obesity can be regarded as a dual interaction [47,48]. Faecal metabolites evaluation provides information regarding the relationship between microbiota and host. Regarding the presence of metabolites, 14 compounds, including lysine, omega-muricholate, and glutamic acid, had been identified [49]. Therefore, a decreased proportion of bifidobacterial associated with the death of butyrate-producing bacteria leads to obesity development [50].

The consumption of probiotics, prebiotics or symbiotics may equilibrate the microbiome, with health benefits in obesity. Studies performed on a human, and animals reported that probiotics can promote weight loss in obesity [51]. Consumption of pickled and fermented foods, particularly vegetables and beans, are an important source of pre-, pro-, and synbiotics, with important benefits on human health [52]. ” Bifidobacteria, lactobacilli, and non-pathogenic fungi are the most used probiotics. Probiotics can confer protection against preeclampsia, gestational diabetes, vaginal infections, maternal and infant weight gain, and other diseases [53]. Therefore, manipulating gut microbiota with the help of probiotics as a supplementary therapy may enhance the immune system. This may be an important strategy to reduce side effects after a specific treatment like those with antibiotics [54]. Prebiotics and probiotics are the most used substances that may balance the microbiome when the microbiome homeostasis is perturbated in several diseases [55]. Therefore, probiotics stimulate the immune system, controlling the synthesis of pro-inflammatory and anti-inflammatory cytokines. Clinical trials which include patients diagnosed with systemic and respiratory infections reported that consumption of probiotics such as L. rhamnosus GG, improves intestinal and lung barrier and even homeostasis. L. rhamnosus GG consumption leads to increased regulatory T cells, ameliorates anti-viral defence, and decrease the pro-inflammatory levels [56]. Studies conducted on obese mice reported that bacteriocin-producing Lactobacillus salivarius UCC118 Bac+ altered the gut microbiota and may reduce the weight gain more effectively than the non-bacteriocin-producing strain L. salivarius UCC118 Bac-. Also, the research team reported elevated proportions of Bacteroidetes and Proteobacteria, and decreased proportions of Actinobacteria, while the proportion of Firmicutes remains the same. The beneficial effects of L. salivarius have been demonstrated even in clinical human studies. The Bacteroidetes–Prevotella–Porphyromonas–Firmicutes ratio, have been increased by the L. salivarius Ls-33. Regarding the effects on obese adolescents, L. salivarius Ls-33 did not have beneficial effects. Moreover, in mice who consume a high-fat diet, Lactobacillus, together with Bacillus amyloliquefaciens SC06, can decrease the Firmicutes/Bacteroidetes ratio, body weight, and hepatic steatosis [57].

Kong C and his research revealed that probiotic supplementation slows down weight Moreover, the study reported that both groups (HFD and HCD) had a reduced microbial diversity, an increased production of butyric acid-producing bacteria, an increased proportion of beneficial bacteria (Lactobacillus, Clostridium sensustricto, Prevotella, and Alloprevotella) and conditionally pathogenic bacteria (Bacteroides, Alistipes, and Anaerotruncu). Probiotics administration significantly balance the bacteria proportions in HFD and HCD groups [58]. Obesity left uncontrolled leads to metabolic syndrome installation, pathology associated with systemic and oral diseases in adults and children [39, 59-62].

CONCLUSIONS

The gut microbiota plays a dual role, having negative and positive effects on human health. In obese patients, perturbation of gut microbiota has been reported. Therefore, the obese patients' gut microbiota is characterized by an enhanced proportion of pro-inflammatory bacteria and a decrease of anti-inflammatory species, representing an important source of inflammation. Diet influences our intestinal microbiota, thus an unbalanced nutrient intake leads to dysbiosis, which is further correlated with proinflammatory cytokines release, and obesity development. In conclusion, the consumption of probiotics and prebiotics restore our intestinal microbiome, with health benefits to either lean or obese persons.

Gut microbiota – new insight in colorectal cancer pathogenesis

Mihăiță Pătrășescu[1,2], Petruț Nuță[1], Raluca S. Costache[1,2], Săndica Bucurică[1,2], Bogdan Macadon[1], Vasile Balaban[1,2], Andrada Popescu[1,2], Roxana Călin[1], Florentina Ioniță Radu[1,3], Mariana Jinga[1,2]

Abstract: *Gut microbiota is a superorganism involved in homeostasis and in pathogenesis. Microbiota composition is influenced by several factors such as: type of birth (cesarean or natural), role of age, role of diet. Pathological consequences of certain type of diet (especially western type of diet) may, in fact, be mediated by gut microbiota alteration. Also few studies have investigated the issue of gut microbiota composition in patients suffering of colorectal cancer, several reports notice relevant differences. Certain pathogenic bacteria in gut microbiota have been extensively studied in relation to their role in colorectal cancer. Thus, Fusobacterium nucleatum, which is abundant in colorectal cancer patient's colon, may initiate the progression from adenoma to adenocarcinoma. A suggested pattern of oncogenesis in colorectal cancer may be represented by this: dysbiosis-inflammation-oncogenesis. A metanalysis that has been published in 2006 concluded a protective role of probiotics in colorectal cancer and in colonic adenoma.*

Keywords: *colorectal cancer, gut microbiota, probiotics*

Human gut harbors a complex and abundant microbial community which is symbiotically linked with host organism and plays a major role in maintaining the homeostasis by the way of fulfilling various functions such as: limiting the number of intraluminal pathogens, functionnal optimization of immunity system, and important contribution to maintaining energy balance.

It is estimated that there are around 1,014 microorganisms in the colon (mostly bacteria) which is 10 fold above the number of eukaryote cell of human body and that contains a 100 fold richer genome than human genome [1]. As a matter of fact we may acknowledge the existence of a true superorganism whose implications in physiology and pathology of human body are continuously revealed by a great pool of scientific data.

Microbiota composition is influenced by several factors such as: type of birth (cesarean or natural), role of age, role of diet.

Pathological consequences of certain type of diet (especially western type of diet) may, in fact, be mediated by gut microbiota changing [2].

It has been noticed that there are significant differences between European children that eat a western diet and African children that eat rural diet rich in vegetal fibers and poor in meat, as concerning the

[1] Carol Davila University Emergency Central Military Hospital, Bucharest

composition of gut microbiota.

Firmicutes genera is prevalent in European children and Bacteroidetes genera is depleted as opposed to African children in whom the ratio is reversed [3]. The real significance of those changes is to be better defined in the near future. Medical literature is abundant in information on this topic, especially about the composition of microbiota in various pathological situations, but the studies published are mostly animal studies and the implications in understanding of pathological mechanisms and in medical practice are ill defined.

The role of gut microbiota played in certain inflammatory ailments (such as inflammatory bowel diseases – IBD) is well known [1]. Important practical consequences may be derived from these data: stool transplant and probiotics treatment [4]. Chronic local inflammation is a risk factor for colorectal cancer (CRC). As a matter of fact patients suffering from IBD have a yearly risk of CRC of 1% after 10 years from the onset of inflammatory disease [4]. It is an answered question as to what extent the composition of gut microbiota is implicated in CRC susceptibility.

Also a few studies have investigated the issue of gut microbiota composition in patients suffering of CRC [1], several reports notice relevant differences. For instance, a study indicated an increased prevalence of Bacteroidetes and Prevotella genera than in general population [5]. Another study which investigated bacterial populations on the surface of colonic mucosa as opposed to luminal bacteria showed that there was an abundance of Faecalibacterium and Dorea species in patients suffering of adenomatous colonic polyps as opposed to those without polyps [6].

Certain pathogenic bacteria in gut microbiota have been extensively studied in relation to their role in CRC. Thus, Fusobacterium nucleatum, which is abundant in CRC patients' colon, may initiate the progression from adenoma to adenocarcinoma [7]. Rubinstein showed that the species of Fusobacterium which produced the virulence factor FadA stimulated epithelial cell proliferation, promoted inflammation and initiated oncogenesis [8]. Similar studies have been published about other components of gut microbiota such as: E. Coli, B. fragilis, S. Gallolyticus (former S. bovis particularly associated with CRC) [8,9,10,11]

Also it is obvious that there is a change in CRC patients gut microbiota composition, it is not clear if those changes are already present before the diagnosis of CRC suggesting a role of risk factor or those changes reflect the consequences of the disease.

From another point of view, the CRC risk factors modify gut microbiota and may elicit the oncogenic process by this route. Several studies have indicated that a meat diet, by the way of microbiota composition alteration, may play an important role in oncogenesis [12,13].

Obesity is a major risk factor in CRC. Many studies showed a certain pattern of gut microbiota change in obese subjects, in animal as well as in human studies [14,15]. Gut bacteria have an impact on peripheral resistance to insulin, systemic inflammatory status and on systemic adiposity by the way of interaction with intestinal epithelial cells. Those interactions are very complex and mutually beneficial. Thus, gut bacteria metabolize various nutrients such as digest-resistant carbohydrates which results in production of short chain fatty acids (mainly butyrate). Gut epithelial cells uses as a main source of energy those fatty acids. Moreover, butyrate may be involved in anti-oncologic effects [16]. Backend noticed, in a mice study, that germ-free subjects experienced a 60% increase in adiposity and a significant increase in peripheral resistance to insulin after 14 days from stool transplant performed from lean mice, in spite of a restrictive diet. Stool transplant from obese mice elicits an even greater increase in total fat mass, which may render a reasonable demonstration about the role played by microbiota in obesity and this may further suggest a role in colonic oncogenesis [15].

A suggested pattern of oncogenesis in CRC may be represented by this: dysbiosis – inflammation – oncogenesis. Alteration of gut microbiota (dysbiosis), as a response to an unidentified trigger, has been studied in animal experimental models with regard to collective or individual role of bacteria in development of inflammation and CRC [17]. The pathogenic

mechanism is still unclear but we may appreciate an involvement of certain receptors of innate immune system responsible for microbial detection [18].

Indirect data on the topic of gut microbiota in CRC are derived from the acknowledged protective role of probiotics. The term of probiotics has been used for several decades but World Health Organization has issued a definition only in 2001: „ live microorganisms that render health benefits when they are administered in proper doses” [19]. Lactic bacteria and Bifidobacteria are among the most known types of probiotics. A metanalysis that has been published in 2006 concluded a protective role of probiotics in CRC and in colonic adenoma [20]. The authors of this metanalysis suggested a cautious use of these data as the interventional type of studies were still not enough to render an unequivoque positive answer.

Recently, Faecalibacterium prausnitzii, a commensal bacterium in gut microbiota that has anti-inflammatory properties, has also been indicated as a probiotic to decrease the risk of CRC [21].

Mechanisms engaged by probiotics in the process of oncogenesis are multiple: cell cycle influences, oxygen reactive species, apoptosis, specific bacterial enzymes, influences on human host metabolome [1]. Probiotics have an important contribution to the development of mucosal associated immune system as it modulates unspecific inflammatory response and it dampens down mucosal inflammation. Probiotics exert also certain effects on dendritic cell, colonic epithelial cells, lamina propria T cells, thus having an impact on adaptive immune system. Perdigon noticed in a mice study, that joghurt (rich in lactic bacteria) hampered the growth of colonic tumors which had been previously induced by mice exposure to 1,2 dimetilhidralazine [22]. Urbanska reached a similar conclusion in another mice study. He showed that yoghurt might reduce the volume of the tumor. Induction of apoptosis may be credited as a major mechanism that mediates the beneficial effects of probiotics against oncogenesis of colonic tumors. Hence, the induction of apoptosis could be seen as a phenomenon of oncologic screening [23].

In spite of all these experimental data from animal models that indicate the fact that probiotics have the potential to stop the development of CRC, systematic studies to show the same benefits in humans are very limited. In a human study about the prophylactic effect of Lactobacillus casei in CRC the conclusion was that two years of continuous administration significantly reduced the incidence of CRC as compared to control group [24]. Recently, in a cohort study that included 45000 subjects over a period of 12 years it has been noticed that large daily amounts of yoghurt reduced the incidence of CRC, suggesting a major prophylactic benefit from long term administration of joghurt [25,26]. Future clinical studies should consider, also, the standardization of probiotics composition, as well as the control of diet, time and frequency of probiotics administration. They should identify the proper biomarkers that may allow monitor of long term effects.

In conclusion, a large and significant pool of data indicates a major role of gut microbiota in CRC oncogenesis as well as in CRC prophylaxis. The majority of studies are, still, animal studies. Those and the few human studies are, never the less, highly suggestive. Unfortunately, we do not know the definition of „normal” composition of gut microbiota, yet. The mechanisms that link dysbiosis and CRC are complex and are related to local and systemic chronic inflammation. Some of the modifiable risk factors in CRC (obesity, diabetes mellitus, and western type of diet) may act, also, through alteration of gut microbiota. The prophylactic role of probiotics may render a powerful mean to significantly reduce the incidence of CRC in the future.

composition of gut microbiota.

Firmicutes genera is prevalent in European children and Bacteroidetes genera is depleted as opposed to African children in whom the ratio is reversed [3]. The real significance of those changes is to be better defined in the near future. Medical literature is abundant in information on this topic, especially about the composition of microbiota in various pathological situations, but the studies published are mostly animal studies and the implications in understanding of pathological mechanisms and in medical practice are ill defined.

The role of gut microbiota played in certain inflammatory ailments (such as inflammatory bowel diseases – IBD) is well known [1]. Important practical consequences may be derived from these data: stool transplant and probiotics treatment [4]. Chronic local inflammation is a risk factor for colorectal cancer (CRC). As a matter of fact patients suffering from IBD have a yearly risk of CRC of 1% after 10 years from the onset of inflammatory disease [4]. It is an answered question as to what extent the composition of gut microbiota is implicated in CRC susceptibility.

Also a few studies have investigated the issue of gut microbiota composition in patients suffering of CRC [1], several reports notice relevant differences. For instance, a study indicated an increased prevalence of Bacteroidetes and Prevotella genera than in general population [5]. Another study which investigated bacterial populations on the surface of colonic mucosa as opposed to luminal bacteria showed that there was an abundance of Faecalibacterium and Dorea species in patients suffering of adenomatous colonic polyps as opposed to those without polyps [6].

Certain pathogenic bacteria in gut microbiota have been extensively studied in relation to their role in CRC. Thus, Fusobacterium nucleatum, which is abundant in CRC patients' colon, may initiate the progression from adenoma to adenocarcinoma [7]. Rubinstein showed that the species of Fusobacterium which produced the virulence factor FadA stimulated epithelial cell proliferation, promoted inflammation and initiated oncogenesis [8]. Similar studies have been published about other components of gut microbiota such as: E. Coli, B. fragilis, S. Gallolyticus (former S. bovis particularly associated with CRC) [8,9,10,11]

Also it is obvious that there is a change in CRC patients gut microbiota composition, it is not clear if those changes are already present before the diagnosis of CRC suggesting a role of risk factor or those changes reflect the consequences of the disease.

From another point of view, the CRC risk factors modify gut microbiota and may elicit the oncogenic process by this route. Several studies have indicated that a meat diet, by the way of microbiota composition alteration, may play an important role in oncogenesis [12,13].

Obesity is a major risk factor in CRC. Many studies showed a certain pattern of gut microbiota change in obese subjects, in animal as well as in human studies [14,15]. Gut bacteria have an impact on peripheral resistance to insulin, systemic inflammatory status and on systemic adiposity by the way of interaction with intestinal epithelial cells. Those interactions are very complex and mutually beneficial. Thus, gut bacteria metabolize various nutrients such as digest-resistant carbohydrates which results in production of short chain fatty acids (mainly butyrate). Gut epithelial cells uses as a main source of energy those fatty acids. Moreover, butyrate may be involved in anti-oncologic effects [16]. Backend noticed, in a mice study, that germ-free subjects experienced a 60% increase in adiposity and a significant increase in peripheral resistance to insulin after 14 days from stool transplant performed from lean mice, in spite of a restrictive diet. Stool transplant from obese mice elicits an even greater increase in total fat mass, which may render a reasonable demonstration about the role played by microbiota in obesity and this may further suggest a role in colonic oncogenesis [15].

A suggested pattern of oncogenesis in CRC may be represented by this: dysbiosis – inflammation – oncogenesis. Alteration of gut microbiota (dysbiosis), as a response to an unidentified trigger, has been studied in animal experimental models with regard to collective or individual role of bacteria in development of inflammation and CRC [17]. The pathogenic

mechanism is still unclear but we may appreciate an involvement of certain receptors of innate immune system responsible for microbial detection [18].

Indirect data on the topic of gut microbiota in CRC are derived from the acknowledged protective role of probiotics. The term of probiotics has been used for several decades but World Health Organization has issued a definition only in 2001: „ live microorganisms that render health benefits when they are administered in proper doses" [19]. Lactic bacteria and Bifidobacteria are among the most known types of probiotics. A metanalysis that has been published in 2006 concluded a protective role of probiotics in CRC and in colonic adenoma [20]. The authors of this metanalysis suggested a cautious use of these data as the interventional type of studies were still not enough to render an unequivoque positive answer.

Recently, Faecalibacterium prausnitzii, a commensal bacterium in gut microbiota that has anti-inflammatory properties, has also been indicated as a probiotic to decrease the risk of CRC [21].

Mechanisms engaged by probiotics in the process of oncogenesis are multiple: cell cycle influences, oxygen reactive species, apoptosis, specific bacterial enzymes, influences on human host metabolome [1]. Probiotics have an important contribution to the development of mucosal associated immune system as it modulates unspecific inflammatory response and it dampens down mucosal inflammation. Probiotics exert also certain effects on dendritic cell, colonic epithelial cells, lamina propria T cells, thus having an impact on adaptive immune system. Perdigon noticed in a mice study, that joghurt (rich in lactic bacteria) hampered the growth of colonic tumors which had been previously induced by mice exposure to 1,2 dimetilhidralazine [22]. Urbanska reached a similar conclusion in another mice study. He showed that yoghurt might reduce the volume of the tumor. Induction of apoptosis may be credited as a major mechanism that mediates the beneficial effects of probiotics against oncogenesis of colonic tumors. Hence, the induction of apoptosis could be seen as a phenomenon of oncologic screening [23].

In spite of all these experimental data from animal models that indicate the fact that probiotics have the potential to stop the development of CRC, systematic studies to show the same benefits in humans are very limited. In a human study about the prophylactic effect of Lactobacillus casei in CRC the conclusion was that two years of continuous administration significantly reduced the incidence of CRC as compared to control group [24]. Recently, in a cohort study that included 45000 subjects over a period of 12 years it has been noticed that large daily amounts of yoghurt reduced the incidence of CRC, suggesting a major prophylactic benefit from long term administration of joghurt [25,26]. Future clinical studies should consider, also, the standardization of probiotics composition, as well as the control of diet, time and frequency of probiotics administration. They should identify the proper biomarkers that may allow monitor of long term effects.

In conclusion, a large and significant pool of data indicates a major role of gut microbiota in CRC oncogenesis as well as in CRC prophylaxis. The majority of studies are, still, animal studies. Those and the few human studies are, never the less, highly suggestive. Unfortunately, we do not know the definition of „normal" composition of gut microbiota, yet. The mechanisms that link dysbiosis and CRC are complex and are related to local and systemic chronic inflammation. Some of the modifiable risk factors in CRC (obesity, diabetes mellitus, and western type of diet) may act, also, through alteration of gut microbiota. The prophylactic role of probiotics may render a powerful mean to significantly reduce the incidence of CRC in the future.

Hashimoto thyroiditis amid COVID-19 pandemic: A clinical study

Dan Pereţianu[1], Eugenia Petrova[2], Mara Carsote[2], Florica Sandru[3]

Abstract: *During COVID-19 era, a special attention was considered for autoimmune disorders (AD), including at thyroid, which are regarded at higher risk knowing that stress and infections might aggravate the pattern of anti-thyroid antibodies as well as thyroid dysfunction. In this study, we aim to analyse how COVID-19 infection influenced the evolution of HT parameters versus patients with HT who did not go through infection. Study design: an observational, bi-centric study in Romania during first 14 months of pandemic. By the end of April 2022, Romania registered 1,047,520 total cases of COVID-19 infection (a morbidity rate calculated for entire Romanian population of 5.23%) with 27,267 total deaths (a lethality rate of 2.6%) and around 2000 new patients a day. From our database of 2210 HT patients, a number of 386 HT subjects were assessed (14 months). Among them, 33/386 patients had a different form of COVID-19 infection. The prevalence of COVID-19 infection among HT patients was 9.35% which is statistically significant higher when compare with official ratio for entire Romanian population (a morbidity rate of 5.23%, z = 3.162, p = 0.00033). A feminine prevalence was identified (89.37%, N=31/33), while age was not different between subgroups (average age over 50 y). At the moment of diagnostic, thyroid function was similar between the two subgroups (⍰2 = 2.02, p = 0.35). We checked ATPOs levels at every visits. Mean ATPO levels at the diagnostic time was 650 UI/mL in group 1 versus 840 UI/mL in group 2 (both groups had very high ATPO values, normal cut-offs below 34 UI/mL) with not statistical significance difference - student ttest (t⍰), p = 0.16. Group 1: the pattern of ATPO evolution was undulatory in 74.07% of patients, decreasing - 3.7%, increasing - 11.11%, unmodified (stationary) - 11.11%, similarly with group 2, meaning that ATPOs had the same profile, regardless the fact that some subjects went through COVID-19 infection. The rate of associated AD was 28.24% (N=2210), COVID-group of 42.42%, non-COVID group of 38.53% (z = 0.44, p = 0.66). In our COVID cohort of 33 patients with HT, we registered the following clinical stages of coronavirus infection: 4/33 patients who were asymptomatic; all women, average age: 65.65 years; 2/33 patients with lack of smell and taste; women, over 65 years old; 14/33 patients with mild form; from 31 years old to 70.5 years old (only one man); 10 patients with a moderate form; all women, from 34 to 71 years old; one 87-year-old male with a severe form; one 50-year old female with a very severe form in addition to a hematologic disease and a history of severe allergic reactions; and a single patient (a 68-year-old, obese female with a severe allergic background) died of COVID-19 infection (thus generating a lethality rate of 3.03%). Conclusion. Our study showed a higher prevalence of COVID-19 infection among HT patients. These individuals do not associate increased levels of ATPO or a elevated prevalence of AD when compare with non-COVID – HT group, and have similar age and sex ratio. Whether HT exposes the subjects to coronavirus infection is an open issue.*

INTRODUCTION

During COVID-19 (coronavirus-disease-year-2019) era, a special attention was payed for autoimmune disorders which are considered at higher risk amid this situation. [1] One of this autoimmune diseases is Hashimoto thyroiditis (HT), also known as chronic lymphocytic autoimmune thyroiditis; for what we know so far, stress and any type of infections are prone to either trigger or aggravate the clinical picture and associated hormonal imbalance of HT. [2] An analysis of chronic thyroiditis correlated with COVID-19 situation currently is approached with different levels of

statistical evidence worldwide. [3-15]

The first patient confirmed with COVID-19 in Romania was registered in 26 February 2020. [16-19] When the first 139 cases were diagnosed, on the 16th of March 2020, it was declared an "Emergency State", which lasted for 2 months, until the 15th of May 2020. [16-19] During that period of time, there were registered 16,437 cases of COVID-19 infection with 1,070 deaths (a lethality rate of 6.5%). [16-19] This was considered as "First pandemic wave" with a peak on the 11th of April 2020 with 523 new cases/day. [16-19] Starting from that day, an "Alert State" was initiated in our country. [16-19] Under these conditions, we had a "Second Wave", from the 15th of September 2020, with a peak on the 18th of November 2020 (a total of 10,629 new cases per day, with a total of 324,094 COVID-19 cases and 8,389 deaths (a lethality rate of 2.59%). This wave followed by a "Third Wave", starting with the 3rd of February 2021, with a peak on the 25th March 2021 with 6,651 new cases per day, with a total of 919,794 cases and a total death number of 22,717 (a lethality rate of 2.47%). [16-19]

Aim

In this study, we aim to analyse how COVID-19 infection amid pandemic influenced the evolution of HT versus patients with HT who did not go through infection.

PATIENTS AND METHOD

Study design

This is an observational (non-interventional), bi-centric study in Romania. The endocrine patients were registered from two medical centres in Bucharest, Romania (Europe). We analysed the patients with HT who were diagnosed with COVID-19 infection compare with those who were disease free during the first 14 months of COVID-19 pandemic.

Evaluation of patients

Based on our files, we registered patients with HT for the last 25 years; these patients previously had a thyroid ultrasound performed on a daily bases and quantitative antithyroperoxydase antibodies (ATPOs) and antithyroglobuline antibodies (ATGs) assays which were performed in our laboratories. HT diagnostic was based on serum ATPOs levels above the normal upper limit (no restriction concerning the level of ATPO elevation in order to sustain the diagnostic of HT). Also, the patients with high ATPOs levels (cut-off of more than 34 UI/mL) and confirmed with HT were evaluated based on thyroid ultrasound to check of if they had specific inflammatory aspects which did not limit the HT diagnostic. Anterior neck ultrasound was performed with a linear probe, long of 4 cm, with 7.5 to 10 MHz.

Our records showed 2,210 patients with traditional diagnostic of HT (based on high ATPOs levels) within the last 25 years. From this database, we analysed the patients who were admitted (as outpatients) during COVID-19 pandemic (from the 16th of March 2020 to 22nd - 27th of April 2022). Overall, we analysed 386 patients with HT (during this mentioned period of 14 months). Some of prior patients were under levothyroxine therapy for associated hypothyroidism (a daily dose of 25 to 125 µg) in order to achieve a TSH (Thyroid Stimulating Hormone) within the normal lab limits. Patients with associated Graves' disease received daily thiamazole (from 5 to 20 mg per day depending on target TSH). Subjects with normal thyroid function did not receive any type of medication/ supplements. The decision of daily drugs was done by each individuals' current practitioner and did not restrict the enrolment of the patients.

The classification of type of COVID-19 infection

We used the WHO classification (Global COVID-19 Clinical Platform), with a few adjustments: Stage 1: asymptomatic; Stage 2: only lack of small and /or taste; Stage 3: mild symptoms (few hours of fever and/or cough); Stage 4: moderate (fever, cough, no lack of oxygen), Stage 5: severe meaning pre-ITU (Intensive Care Unit) hospitalization, oxygen saturation under 93%, above 85%, Stage 6: very severe form requiring an ITU hospitalization (oxygen saturation under 85%); Stage 7: death.

COVID-19 information for studied population

In order to assess the information concerning COVID-19 infection we analysed the medical records of the patients from other medical departments (which were provided by the patients themselves). Some of them were evaluated as outpatients in Endocrinology Department, and some through telemedicine. General information amid infected cases in our country were achieved by accessing public sources (universally free downloads). [16-19]

Statistical analysis

We used z Fisher test on ratios, ⍰2 test on discreet data, and Student t test on continuous data, as appropriate to analyse the differences studied between groups. Statistical significance was considered at $p < 0.05$.

RESULTS

Associated COVID-19 pandemic information (Romania)

Until the 22nd April 2022, Romania registered 1,047,520 total cases of COVID-19 infection (a morbidity rate calculated for entire Romanian population of 5.23%) with 27,267 total deaths (a lethality rate of 2.6%) and around 2000 new patients a day (see Figures 1-3, universally available free download from Public Source: https://www.worldometers.info/coronavirus/country/romania/.)

The impact of SARS-CoV-2 on patients previously diagnosed with TH

From our database of 2210 patients with HT, a number of 386 subjects were assessed during the first 14 months of COVID-19 pandemic. We registered 33 (out of 386) patients who had a different form of COVID-19 infection. All the data from these patients were compared with the data from our patients with HT who were evaluated during the same period of time but did not have COVID-19 infection. We the patients' profile in order to detect if there any differences between the two subgroups. The interval of time between COVID-19 infection and the moment we performed the endocrine evaluation varied from days to 6 months. (Table 1)

Table 1: Clinical and biological data from patients with Hashimoto thyroiditis: patients who had a COVID-19 infection versus subjects without infection

Parameter	Patients with COVID-19 infection	Patients without COVID-19 infection	Statistical significance
Number = 386	33 (9.35%)*	353 (90.65%)	z = 3.62, p= 0.00033*
Women = 345 (89.37%)	31 (93.94%)	314 (88.95%)	χ^2 = 0.42, p = 0.63, NS
Men = 41 (10.67%)	2 (6.06%)	39 (11.05%)	
Age (years) at COVID-19 diagnostic (mean) Current age at evaluation (mean)	52.82 58.43	51.36 55.99	p = 0.57, NS p = 0.36, NS
Euthyroidism at the diagnostic vs. current time	10 (30.30%) vs 24 (72.73%)	138 (30.09%) vs 205 (61.19%)	z = -0.74, p = 0.46, NS z = 1.3, p = 0.2, NS
Hypothyroidism at the diagnostic vs. current time	17 (51.52%) vs 8 (24.24%)	177 (50.14%) vs 124 (37.01%)	z = -0.22, p = 0.82, NS z = -1.42, p = 0.15, NS
Hyperthyroidism at the diagnostic vs. current time	6 (18.18%) vs 1 (3.03%)	38 (10.76%) vs 6 (1.79%)	z = 1.5, p = 0.14 z = 0.49, p = 0.62
ATPO levels (normal level < 34 UI/mL)	650 UI/mL	840 UI/mL	p = 0.16 (NS)
History of miscarriage	2 (6.45%)	30 (9.55%)	z = -0.58, p = 0.56, NS
Association with other immune/autoimmune conditions	11 (42.42%)	136 (38.53%)	z = 0.44, p = 0.66, NS

** applied to the morbidity in general population, NS = nonsignificant; vs=versus; ATPO= Anti-thyroperoxidase antibodies*

Prevalence analysis

The prevalence of COVID-19 infection among our patients which was registered during the studies 14 months was 9.35%. We compare this ratio with the official ratio of COVID-19 for entire Romanian population, the morbidity (see above), was 5.23%. For this comparison we used the z test from Fisher equation, which compare ratios. From this point of view, the prevalence is higher, the statistical significance was z = 3.162, p = 0.00033.

Gender prevalence

A feminine prevalence was identified in our cohort: 89.37% were women, and 10.67% were men. During the first 14 months of pandemic, 31 women and 2 men had a COVID-19 in addition to previously diagnostic of HT. When comparing gender prevalence with general data, there was no statistical significance (⍰2 test = 0.37, p = 0.79). (Table 2)

Age analysis

Mean age of 33 patients was 52.82 years at the diagnostic while the subgroup with HT without infection had an average age of 51.36 years at the diagnostic time and 55.99 years at the current time with not statistical significance difference. (Table 2)

Thyroid function

We analysed the thyroid function at initial diagnostic time and current moement, when patients were revised. Hypothyroid patients received levothyroxine and some become euthyroid; hyperthyroid patients received thiamazole, and mostly became euthyroid under this therapy. All these data were compared with the group without COVID-19 infections/14 months. All patients with high ATPO (anti-thyroperoxidase antibodies) who had hyperthyroidism had also positive TRAB (TSH Receptor Antibodies) according to a level higher than 1 UI/ml (co-occurrence of HT and Graves-Basedow's disease).

When analysing all cases in the same time by χ^2 test, there was no differences concerning the aspect of thyroid function both at the diagnostic time and the current time between patients from group 1 versus group 2 (χ^2 = 2.02, p = 0.35). Similarly, z analysis on thyroid function (separately for euthyroidism, hypothyroidism and hyperthyroidism distribution) showed no statistically significance difference. Therefore, the thyroid function, either at the diagnostic time or at the current visit, had no importance in catching the viral disease. (Table 2)

Table 2: The parameters of patients with chronic Hashimoto thyroiditis who had an episode of COVID-19 infection during the last 14 months

	Gender	Age at diagnostic moment	Current age	ATPO average UI/mL*	ATPO evolution	Thyroid function a)	Current thyroid function	Specific treatment for thyroid dysfunction	COVID-19 clinical form	Other observations. Anti-SARS-CoV antibodies (if available)

32	W	41	41	125	-	HOT	-	-	Mild	
33	W	56	68	2772	Undulatory	HOT	HOT	Substitution	Death	

Abbreviations: EUT = euthyroidism, HOT = hypothyroidism, HYT = hyperthyroidism, NT = no specific treatment, ITU = intensive therapy unit, ACAb = anti-SARS CoV antibodies; NA = not available; "substitution" means levothyroxine replacement for hypothyroidism

** Upper normal limit = 34 UI/mL; a) Thyroid function at the moment of COVID-19 infection*

ATPO evolution

We checked ATPOs levels at every visits. Mean ATPO levels at the diagnostic time was 650 UI/mL in group 1 versus 840 UI/mL in group 2 (both groups had very high ATPO values) with not statistical significance difference according to Student test (t_α): p = 0.16.

We described the ATPOs evolution in 5 ways: undulatory, increasing, decreasing, non-evolutive (stationary) and normalization below mentioned cut-off of 34 UI/mL. Accordingly to this description, in COVID-19 patients, we observed the following ratio: undulatory = 74.07%, decreasing = 3.7%, increasing = 11.11%, unmodified (stationary) = 11.11%, and normalized values of ATPO = 0%. In non-COVID patients the ratios were: undulatory = 69.04%, decreasing = 12.13%, increasing = 8.37%, unmodified = 6.28%, normalized = 4.18%. ATPO evolution did not reach a statistical difference (χ^2 = 0.43, p = 0.1.67), meaning that ATPOs had the same pattern, regardless the fact that some subjects went through infection. (Table 2)

Infertility and miscarriage issues

In all our registered patients (N = 2210) the miscarriage was registered in the medical history of 150 patients (N= 7.33%). In non-COVID group, miscarriage was registered in 30 patients (9.55%). In COVID-19 group miscarriage was registered in only 2 patients (6.45%); z = -0.44, p = 0.66, NS.

Other immune/autoimmune associations

HT is frequently associated with other immune disturbances, which could be involved in an inadequate immune response to viral infections. In all our patients (N = 2210), the prevalence of immune/autoimmune associations were registered in 28.24% patients. In non-COVID group, the rate was 38.53%. In COVID-19 group, this rate was 42.42% patients (z = 0.44, p = 0.66).

COVID-19 infection: the clinical severity in HT patients

In our COVID cohort of 33 patients with HT, we registered the following clinical stages of coronavirus infection: 4/33 patients who were asymptomatic; all women, average age: 65.65 years; 2/33 patients with lack of smell and taste; women, over 65 years old; 14/33 patients with mild form; from 31 years old to 70.5 years old (only one man); 10 patients with a moderate form; all women, from 34 to 71 years old; one 87-year-old male with a severe form; one 50-year old female with a very severe form in addition to a hematologic disease and a history of severe allergic reactions; and a single patient (a 68-year-old, obese female with a severe allergic background) died of COVID-19 infection (thus generating a lethality rate of 3.03%) (Table 2)

SARS-CoV antibodies (post-infection or post-vaccine) in patients with HT

Only 17/386 patients had been vaccinated during the last 4 months of study protocol. Only 5/17 had been tested for antibodies against S-protein. The data were listed in AU/mL (1 AU/mL = 0.142 BAU/mL, according to WHO standards): 2500, 4200, 2000, 45300 and 5400. Only 2 patients with COVID-19 infection and chronic thyroiditis performed these antibodies after disease. The levels were of 4600 AU/ml, respectively of 18000 AU/mL, higher than seen in patients without a history of coronavirus infection.

DISCUSSION

For the first 14 months of pandemic, studied population showed a higher rate of COVID -19 infection when compare to entire Romanian population based on official records. [16-19] The fact that patients with thyroid conditions, including those antibodies - related, are at higher risk of contracting coronavirus infections is controversial up to the current level of scientific information. [20-30] As expected for a thyroid autoimmune condition, we had an overall female prevalence, including in COVID group. A higher susceptibility and a more severe coronavirus infection was suggested for males, unless autoimmune background or other particular sub-groups. [31-33]

We had an average age over 50 years on both subgroups. Generally, COVID-19 infection has been reported at any age, but seniors older than 65 years are at higher risk. [34-36]

We had a subgroup with individuals associating two autoimmune thyroid diseases: HT and Graves-Basedow's disease. Notably, in the COVID group there are slightly more patients with hyperthyroidism at the diagnostic time (18.18%) that in non-COVID patients at the diagnostic time (10.76%). Without reaching a statistical significance (p >0.05), these data suggest that hyperthyroidism (which means association of Graves-Basedow disease with HT) could add some pathogenic factors to increase the risk of SARS-CoV-2 infection. However, these factors do not seem to be related to thyroid function, but more to immunological association between HT and Graves-Basedow's disease. Coronavirus might be triggered by autoimmune hyperthyroidism. [37] We evaluated the function and the antibodies' profile concerning these two diseases; also, all the subjects had an ultrasound done but we did not introduce in final analysis the reports of ultrasound data. Generally, thyroid ultrasound is a key tool of evaluating the patients with these conditions. [38-44]

In COVID-19 group, the miscarriage rate was of 6.45%, which is not different from entire HT cohort. Some data suggested that females going through coronavirus infection might experience a higher rate of miscarriage which is not confirmed in our cohort. [45] Also, the group of persons experiencing the infection have the similar profile of autoimmune co-morbidities. The autoimmune background, however, influences the immune response amid infection. [46-48] Overall, our patients had a mild COVID-19 symptomatology, only 3 patients experiencing a severe form. Therefore, HT did not aggravate coronavirus evolution as other endocrine conditions (like diabetes mellitus or obesity).

As limits of the study we mention: one aspect involves the fact that we did not take into consideration the post-vaccine status which include a small number of subjects among studied subgroups; and, also, the small sample size of the cohort.

CONCLUSION

Our study showed a higher prevalence of COVID-19 infection among HT patients. These individuals do not associate increased levels of ATPO or an elevated prevalence of AD when compare with non-COVID – HT group, and have similar age and sex ratio. Whether HT exposes the subjects to coronavirus infection is an open issue.

Health sector organization to respond to a bioterrorist attack

Athanasios Zafeirakis[1], Panagiotis Efstathiou[2]

Abstract: *Bioterrorism constitutes a major health threat to global communities, with many specific features that carry the potential to extraordinary stress the Public Health Sector (PHS) of any country, because of the needs of resources and of a coordination network required for a successful response to such incidents. Bioterrorism incidents of the near past prove that public mortality and morbidity can be further reduced if a functional protocol would allow first responders, hospitals, and officials of the PHS to steer more efficiently the public expectations. At the national level, the PHS director is responsible to mobilize and coordinate that network of the critical human, financial and logistical resources during the preparedness and response phases after a bioterrorist attack to mitigate its effects. Both these phases include many specific functions and responsibilities, which will be beneath analyzed.*

Keywords: *bioterrorism, public health sector, health preparedness*

BACKGROUND

Bioterrorism is the deliberate use of biological agents to disseminate life-threatening diseases to threaten or devastate a population [1]. The bioterrorist threat consists of a rapidly growing and perhaps the most frightening menace to world health security [2]. The weaponized application of pathogens to disorder populations has been established throughout history [3]. However recently, the profound development of bio-molecular engineering combined with the worldwide proliferation of high-level biosafety laboratories has aroused concern about the increased accessibility of biotechnology [4] and potential misuse of biological agents [5]. Bioterrorism manufacture requires just culture samples, the means to grow, purify, stabilize and disseminate them [6].

The motives underlying bioterrorist incidents of the last years have been nationalistic objectives, revenge, or a mix of paranoid – conspiratorial – apocalyptic prophecy [7]. Additionally, large terrorist organizations such Al-Qaida would always seek ways to acquire biological weapons [8].

The biological agents considered suitable for terrorism should have high inter-human infectiousness, high morbidity and/or lethality, ease of manufacture, storage, and delivery in adequate quantities, environmental stability after dispersion, and absence of effective treatment [9].

Most of the abovementioned characteristics are easily achievable and that raises concerns about the devastating power of biological weapons, because of various reasons: they disseminate in various ways, extremely small quantities of them are lethal, manufacture information is readily obtainable, and a bioterrorist attack can initially be covert since the appearance of symptoms and illness will lag for several hours or days [10].

Bioterrorism agents are classified into bacteria and viruses and yet into three categories; A, B, and C, depending on the ease of dissemination, severity of illness caused, and ability

to cause death [11]. Of those, microorganisms of Category-A (i.e. anthrax, botulism, plague, smallpox, and viral hemorrhagic fevers), carry the potential to extraordinary stress the PHS, because:

1. The initial release of the bioterrorist agent could go undetected until the onset of disease, creating a sudden influx of severe illness;

2. Incidents that result in impairment of food and water supplies, as well as transportation and communication barriers, may gravely affect the national stability;

3. Contamination risks and subsequent fears of exposure may further complicate recovery operations and cause civil disorder [12].

Up to now, bioterrorism remains a challenge for the PHS of every nation, mainly due to the need for resources and a coordination network required for a successful response to an incident [13]. At the national level, the PHS director is responsible to mobilize and coordinate that network of the critical human, financial and logistical resources during the preparedness and response phases after a bioterrorist attack. Both these phases include specific functions and responsibilities of PHS, which will be beneath analyzed.

PREPAREDNESS PHASE

Risk Assessment

Among weapons of mass destruction, biological agents are much more destructive than chemical weapons, including nerve gases, whilst under certain conditions, biological weapons can be equally devastating to nuclear ones. For example, according to a traditional disaster simulation model [14], a few kilograms of anthrax in a dense urban area can kill as many people as a Hiroshima-size atomic bomb, or cause even more casualties when considering the current suburban living situation of a western Metropolis, combined with favorable upwind conditions [15].

Risk assessment is a multidisciplinary activity, aiming at identifying those who may wish to use biological weapons against the population, the agents that may be used, and the circumstances under which they may be used. Risk assessment of biological threats often involves modeling approaches based on certain risk assumptions. To understand these risks, planners assess them as a function of their likelihood to occur, their potential consequences, and the possible measures that could be taken to control them, based on an understanding of existing surveillance data, the literature, past experiences, and opinions of experts [16].

Intelligence

Preparedness for bioterrorist attacks includes international collaboration for the secure exchange of sensitive information regarding the capabilities of terrorists [2]. Accurately predicting potential biologic threats is difficult without the implementation of intelligence data, adequate funding [17], strategies of data- and cyber-security, and expanding use of electronic information, reporting and surveillance systems [18]. Furthermore, networked video cameras and advanced software designed to verify important intelligence information have become powerful tools for counterterrorism operations [19]. Notification to WHO is required for all cases of sufficient seriousness, such as diseases with severe public health impact, risk of international spread, cases of unusual or unexpected nature, and of course all cases of category A diseases, which constitute a "public health emergency of international concern" [20].

Disease Surveillance

The cause of a bioterrorist disease may be difficult to determine, especially if the initial cases are few. Because of rapid progression to illness and the potential for dissemination of bioterrorist agents, authorities of the PHS should apply accurate, sensitive, and specific surveillance systems to promptly recognize non-specific disease patterns that might indicate the early manifestations of a biological attack. That can be accomplished through two pillars; epidemiological and syndromic surveillance.

Epidemiological surveillance

Following a confirmed case of biological exposure or clusters of unusual symptoms or diseases detected by PHS surveillance, forensic epidemiology tracks back to identify the population at risk. This procedure is called the epidemiological investigation and uses descriptive, analytical, and molecular epidemiologic tools to identify the source and possibly to prevent further events [21, 22]. For that to be accomplished, epidemiological models encompass the potential agent to be used, the specific geographic location of an attack, the level of preparedness, and early intervention on a local and national level. Epidemiologic principles must be used to assess whether a patient’s presentation is typical of an endemic disease or is an unusual event that should raise concern. An epidemiological alert system should include multiple sub-systems regarding disease reporting, laboratory network surveillance for specific pathogens, sentinel hospital surveillance for infectious diseases based on primary healthcare data, and a rapid response system with a 24 h/7 d epidemic response team [23].

Syndromic surveillance

The concept involves real-time collecting and analyzing statistical data in a given population, focusing on symptoms rather than laboratory confirmation of diagnosis. Syndromic surveillance systems register suspicious or confirmed cases reported by physicians, and the data are used to monitor the progress of a bioterrorism outbreak [2]. The technique may be affected by various factors, such as data selection criteria, seasonality, size and dispersion of the infected population, the incubation period, selection of statistical detection thresholds, duration of follow-up, access to diagnostic practices or reference laboratories, and reporting procedures; all these results in potentially false alarms and overuse of resources to investigate them [24]. Specificity for distinguishing random variations of ordinary illnesses from bioterrorist attacks may be low when the early symptoms of bioterrorism-related illness overlap with those of many common infections, whilst respective sensitivity may also be low if detection thresholds are reduced to enhance specificity [25]. Lastly, syndromic surveillance is planned to enhance, rather than replace, existing diagnostic tools to epidemic detection [26].

Early Warning and Response System (EWRS)

Numerous biological agents may be used in bioterrorism; terrorists might use combinations of them, common or new, drug-resistant or genetically engineered pathogens, or attack in more than one location simultaneously. Early detection and response to highly contagious biological agents are hence crucial. That can be accomplished through an EWRS, i.e. a rapid web-based alert system used for exchanging information on health threats resulting from the deliberate release of a chemical, biological and radiological agents, but mostly for monitoring epidemics. A major benefit of global collaboration at a technical level is the development of trust networks among experienced scientists and clinicians, for both natural and intentional outbreaks [27].

Emergency Planning

Terrorist attacks are more frequently covert compared to bombings or even chemical attacks. That is an intrinsic feature of bioterrorism, due to the incubation period of pathogens that brings a delay between exposure and onset of symptoms and consequently, between the attack and the involvement of PHS and civil security agencies [28]. The importance of emergency planning lays in the fact that public health infrastructure should be prepared to confront a rapid sequence of emergency events, including a delayed massive wave of illness, rapid dissemination in the population, and the need for prevention strategies, analyzed below.

Laboratory Preparedness

A solid laboratory network would enable quick and accurate detection and subsequent response to biological threats. The response capacity of those laboratories is classified into four Biosafety Levels (BSL); from BSL-1 (clinical laboratories with minimal biosafety requirements), up to BSL-4 (implementing the highest biosafety standards), according to their scientific background, expertise, and infrastructure to support the diagnostic needs of a highly hazardous biological event [4]. During such, a proper laboratory network enables the following functions:

1. Activating all BSL laboratories nationwide.

2. Prioritizing and sharing information among sentinel laboratories and PHS officials on an emergency, 24/7 day basis, to ensure that the public received precise and prompt messages [18].

3. Recognizing and responding to any covert event involving the collection, preservation, transport, and testing of highly infectious human specimens according to uniform guidelines for handling samples of pathogens of public health interest [29].

Food and Water

Biological agents constitute a major concern regarding the safety of food [30, 31]; contamination of water with biological agents should be also considered, albeit that is improbable to be the major target of bioterrorism, due to chlorination, dilution, and the need for large quantities of the agent to cause a significant biological threat [32]. Nevertheless, quantities far less than a kilogram of botulinal toxin, for example, in the main water supply of a city may cause 28-40,000 deaths, depending on how early symptoms will be recognized and remedial measures will be applied [14].

Stockpiling

The strategic medical stockpile of a country is a national repository of vaccines, drugs (antibiotics, antidotes, etc), and general medical supplies that can be deployed to areas affected by various sorts of public health disasters, including bioterrorism. In the case of the dissemination and subsequent detection of a biological agent, strategic stockpiles of respective medication against the agent should be provided to the affected area within less than 24 hours; subsequently, the medical countermeasures should be appropriately dispensed in the affected community within another 24 hours [33]. Strategic stockpiling has to be considered within the framework of cost-effectiveness;

stockpiling of pharmaceuticals with a sort expiration date may be costly and problematic since the turnover inventory would require a significant monetary amount to maintain stockpiling facilities for continuous checking and renewing [34].

Training

Improved awareness and readiness during a bioterrorist attack include among others education of all medical personnel, especially primary-care providers and first responders to patients affected by a biological attack35. Training inserts knowledge about basic epidemiologic principles, disease patterns, clinical information on diagnosing and treating infected patients [36] and should be refreshed periodically with large-scale exercises to ensure that skills remain up-to-date [37]. Additionally, analysis of actual previous incidents provides precious information regarding proper response. Most importantly, the lessons learned should be incorporated into future planning to identify areas of improvement. Finally, education of health departments and the community on biosafety items, including information for crisis-phone hotlines, contributes to mitigating the negative health effects of a bioterrorist attack [38].

RESPONSE PHASE

Detection-Verification

Prompt diagnosis should be urgent in a probable bioterrorist incident, because for both health and security reasons [39]. The earlier a dissemination is detected, the faster the response and the lower the morbidity and mortality rates. Apart from significant awareness by the PHS, this also requires advanced diagnostic technology. Highly sensitive and specific and yet portable laboratory diagnostic systems are nowadays available to a greater extent than a decade ago, enabling a faster, cheaper, and more accurate verification of the infectious agent. Moreover, increased networking and collaboration of higher-level biosafety laboratories also improve response to biohazards [40]. The critical factors in reducing mortality following a biological incident were found to be early detection of exposure, registering of cases, and dispensing capacity at local and national levels [41, 42]. The verification of a possible bioterrorist attack should fulfill most of the following epidemiological criteria [43]:

1.Occurrence of a specific epidemic disease with similar symptoms in a discrete population;

2.Single case infection caused by an uncommon or class A biological agent;

3.Unusual disease for a specific geographic area or a specific age group;

4.Unusual season of transmission;

5.Many unexplained disease or death incidents;

6.Unusual high level of disease severity with resistance or response failure in standard treatment;

7.Unusual exposure routes of a “known” pathogen;

8.Higher incidence of occurrence in certain area zones, depending on whether the biological agent was released in- or outdoors;

9.Relevant claims by terrorists of a bioterrorism attack or existing intelligence for a potential threat.

Coordination

Biodefense is a complex procedure requiring a multidisciplinary approach. In any bioterrorist incident, interoperation mechanisms between major local, national and international, health- and non-healthcare agencies must be applied. Coordination should be reinforced and biodefense protocols effectively integrated into existing plans [10]. Government stakeholders called to react and collaborate to a bioterrorism incident include policy makers, law enforcement officials, emergency responders of PHS, special centers from scientific, research, forensic, and professional societies and technicians, along with the commercial branches of medical, safety, and decontamination equipment suppliers [28]. In any case, the management of a large-scale bioterrorism outbreak is well beyond the resources and capabilities of most countries; thus many lives can be saved in bioterrorist outbreaks by early mobilization of large-scale international assistance by W.H.O. Furthermore, many national armies afford special Chemical-Biological-Radiological (CBR) units, able to respond to a bioterrorism event; these have the means and often the war expertise to detect, verify and neutralize biohazard threats and to decontaminate victims and areas exposed to such agents.

Rapid Response

Following alleged or genuine dissemination of biological agents, a large number of people will probably seek medical care. Fear and panic are expected in symptomatic patients, yet also in involved health personnel of public hospitals and private clinics, who may be the first to recognize a biohazard outbreak and initiate a response. A broad network of communication towards many stakeholders must then be rapidly activated [44]. Moreover, a plan dealing in detail with the possibility of great numbers of people who concurrently might seek medical care, along with means for psychological support and medical treatment is of utmost importance in the triage rapid response process conducted by various health care professionals. These should operate according to the national SOPs regarding response to the outbreak of a biological agent [18]. Unfortunately, the mobilization of a specialized CBR unit can never match the 24-hour availability and general emergency-management experience of existing emergency response and public health services, whilst the use of CBR protective equipment also requires special training and the adaptation of existing procedures for emergency management [45]. Furthermore, in case of risk for international dissemination of the disease, the International Health Regulations (IHR) should be implemented to prevent the worldwide spread of diseases [46].

Mass Prophylaxis/Infection Control

For most biohazard agents, specialized testing is necessary by PHS specialists or laboratories. Then, vaccination and/or treatment with antibiotics or antitoxins must be started early for viral agents and bacterial diseases. Before undertaking a mass prophylaxis plan, the PHS should identify the population at risk, the sort and the availability of medication to be applied, and the mechanism of administration of such a plan. The decision to apply a mass prophylaxis plan is based on various factors, such as data from epidemiological analysis, hospital bed availability, availability and determination of the quantities of drugs required to support the plan, immunity delays till antibodies development, side-effects of a massive immunization and the estimated number of exposed or ill people [47]. For starting mass prophylaxis, the following admissions should be considered:

1. An adequate stockpile of vaccines and medications is maintained at the national level;

2. The biohazard situation is anticipated to (or already did) overwhelm the regular public health care system;

3. There are shortfalls in local capacity to dispense disease-specific health care services;

4. Multiple biohazard incidents in many locations are already involved with, or without parallel requests for specialized health care provision;

5. A request for international aid has already proceeded.

Vaccination or prophylactic antibiotic treatment of healthcare providers may also be sound, especially in the biological threat of category A biohazard agents, since the occurrence of infection in that cohort will not only severely compromise the ability of PHS to manage the incident, but will also lead the population to the erroneous perception that health care personnel constitute a high-risk source of infection [48].

Personal Protection/Decontamination Issues

During the spread of an aerosolized biological agent, the primary route of exposure will be via the airways and respiratory tract. Respiratory protection will then be the most important component of physical protection. Furthermore, all patients in healthcare facilities with suspected or confirmed bioterrorism-related illnesses should be managed to utilize standard precautions; these are designed to reduce transmission from both recognized and unrecognized sources of infection in healthcare units [49].

Adequate procedures for routine cleaning, disinfection, contaminated waste disposal, and sterilization of equipment and environment should also be available [50]. For category, agents additional precautions may be needed to reduce the likelihood of transmission. Since in most bioterrorism scenarios anthrax is considered the most likely agent to be dis¬seminated, it is worth noticing that anthrax spores can persist in the environment for months or even years, which requires careful evaluation of the decontamination process [51].

Protection of health-care personnel against infection remains particularly problematic; personal protective equipment should be affordable, effective, and available to use with minimal training and under harsh environments [52]. If agents of contagious diseases are released, standard precautions include basic hygiene and infection-control measures, e.g. gloves, hands-washing (whether or not gloves are worn), PPE masks with eye protection (or face shield), and disposable gowns. In parallel, avoiding as possible direct contact with secretions from infected individuals, keeping exposed persons away from public places, and isolating suspected or symptomatic cases, may be essential in limiting secondary spread. These guidelines may though be impractical in case the number of patients presenting to a healthcare facility is too large to allow routine isolation strategies. The fact that in a mass bioterrorism incident many victims may go to hospitals on their initiative has important implications for the application of triage and decontamination protocols. Grouping affected patients who present with similar syndromes into a designated section of a clinic may be a vital alternative to the dissemination of infection. Community containment strategies, including isolation and quarantine, are the ultimate measures to prevent further transmission. Isolation and quarantine are optimally performed voluntarily, but basic legal authority should be in place for mandatory isolation and quarantine of people and communities when necessary to protect public health [53].

Communication in crisis

Public preparedness and response capability relies greatly on efficient information dissemination in a clear, reassuring, and unemotional language. That chain of mostly non-confidential intelligence contains readily apprehensible, explicit, and comprehensive instructions of clinical and epidemiological information and communication channels, discouraging the parallel overreaction of the public after an incident. The population should also be told what signs and symptoms to watch out for and whom to call or where to go if they appear. If specific preventive measures are available to mitigate exposure and infection, the public must be clearly and rapidly informed. Failure to provide a clear public information flow-line may enhance anxiety, fear, and misinterpretations, mainly among citizens who feature non-specific symptoms of exposure to a possible biological agent and that may result in local health facilities becoming overwhelmed by uninfected or panicked patients. Convincing and trustable spokespersons, including respected clinicians, skilled scientists, and public authorities must be able to represent the PHS at all stages of the crisis, also taking into account that the global distribution of social networking increases the dissemination of false or misleading information [54].

Mass Fatality care

During a bioterrorist outbreak, laboratories that receive or dispose of suspicious human body specimens must be informed of relevant clinical and operational protocols. Autopsies should be conducted under full personal protective measures, especially when there is an increased risk of aerosolization or splatter of infectious liquids [44]. Concerning management of bioterrorism fatalities, morgue and funeral protective planning should also be implemented along with prompt and accurate electronic reporting details [18].

Psychological Aspects

The psychological impact, even from a minor bioterrorism-related event may be disproportionately strong55. After such an attack, panic can well affect both victims and healthcare personnel. Psychological reactions following a bioterrorist attack include fear, anger, panic, inappropriate or unrealistic worry about possible contagion or illness, social withdrawal, depression, or demoralization. To handle patient and public fears, the psychological preparedness for bioterrorism should aim at minimizing panic by offering a clear explanation of risks and medical support, and by avoiding unnecessary isolation or quarantine. Furthermore, excessive anxiety in unexposed individuals, experiencing objective but irrelevant clinical symptoms should be treated with non-medical psychological support or on occasion with anxiolytic medication administration. Concerning in particular the healthcare workers, their fears can be managed by bioterrorism readiness education, protection plans, and encouragement of participation in acting field-level roles (e.g. disaster triage volunteering) [56].

CONCLUSION

Increased preparedness, response planning, investments, training, and exercises constitute perhaps the best defense of PHS to mitigate the effects of bioterrorist attacks. Most importantly, citizens must always be aware of a possible deliberate biological contamination and how to respond appropriately. Bioterrorism incidents of the near past prove that public mortality and morbidity can be further reduced if a functional protocol would allow first responders, hospitals, and officials of the PHS to steer more efficiently the public expectations.

Heart failure with preserved ejection fraction: A review

Ruxandra N. Horodinschi[1], Anca Pantea Stoian[2], Dragoș Marcu[1,3], Raluca S. Costache[1,4], Camelia Diaconu[1,5]

Abstract: *Heart failure is the final stage of evolution of a large number of cardiovascular diseases and represents a health problem worldwide, due to increased prevalence of cardiovascular diseases. The patients with heart failure with preserved ejection fraction (HFpEF) represent about a half of the patients with heart failure and the prevalence of HFpEF is on the rise. HFpEF is mainly a disease of the elderly patients, who have numerous cardiovascular diseases – hypertension, myocardial ischaemia, atrial fibrillation, valvular disease, and also non-cardiovascular comorbidities, such as obesity, diabetes mellitus, chronic kidney disease, chronic obstructive pulmonary disease, and obstructive sleep apnoea. HFpEF is more prevalent in women than in men, but women have a better prognosis than men. The pathophysiological changes that appear in HFpEF are: ventricular stiffening, cardiomyocite hypertrophy and hypercontractility, myocardial fibrosis and inflammation, which lead to abnormal diastolic function with delayed relaxation and inappropriate filling, in the presence of a normal systolic function of the left ventricle. The diagnosis of HFpEF is based on clinical, echocardiographic and biological criteria. In contrast to HFrEF, there is no effective treatment for HFpEF. The treatment of HFpEF includes diuretics for clinical improvement and treatment of comorbidities. The prognosis of patients with HFpEF is similar with those with HFrEF. Currently, the main objectives of the treatment in patients with HFpEF are to improve clinical status and decrease hospitalizations. Further studies are needed to establish an effective treatment to increase survival in these patients. Therefore, HFpEF continues to be a challenge for clinicians regarding the optimal therapy..*

Keywords: *heart failure with preserved ejection fraction, diastolic dysfunction, myocardial fibrosis, natriuretic peptides*

INTRODUCTION

Heart failure is the final stage of evolution of a large number of cardiovascular diseases. Heart failure is a major health problem worldwide, due to increased prevalence of cardiovascular diseases and prolonged survival of some categories of patients with cardiovascular diseases, after successful treatment of their conditions.

The most frequent causes of heart failure are: myocardial ischaemia, valvular diseases, arrhythmias, atrio-ventricular conduction disorders, myocarditis, pericarditis. Often, heart failure has more than one cause. It is extremely important to determine the aetiology of heart failure in order to establish the specific therapeutic options (for exemple to reduce

heart rate in tachyarrhythmias, to replace a valve in valvular disease, revascularization of the coronary arteries in patients with myocardial ischaemia, etc.) [1].

Currently, heart failure is classified into heart failure with reduced ejection fraction (less than 40%) - HFrEF,mid-range ejection fraction (between 40-49%) – HFmrEF, and preserved ejection fraction (≥ 50%) – HFpEF1. HFmrEF is a new category of heart failure, first introduced in the classification of heart failure in 2016, in the European Society of Cardiology Guidelines [1].

HFmrEF is usually studied in trials along with HFpEF, so in this paper we will use the terminology of HFpEF, including both entities. Until now, the majority of clinical trials regarding the treatment of heart failure have focused on patients with HFrEF. While in the case of HFrEF, it had been proven that the treatment can reduce both morbidity and mortality, in the case of HFpEF there is no drug which can reduce mortality or morbidity. This is why HfpEF is more challenging for the clinician regarding the diagnosis and treatment.

Patients with HfpEF associate many comorbidities, such as hypertension, diabetes mellitus, vascular disease, atrial fibrillation, metabolic syndrome, chronic kidney disease, which complicate even more the evolution of HFpEF and increase the risk of mortality.

PREVALENCE OF HFpEF

In the last years, the prevalence of HfpEF increased, because of the demographic changes and the changes in the risk factors prevalence, such as the increasing prevalence of hypertension, atrial fibrillation and diabetes mellitus that are all risk factors for HFpEF [2]. HFpEF currently affects more than 7 million people in Europe and is the only cardiovascular condition that has increasing incidence and prevalence [3]. The increasing prevalence of HfpEF can also be a result of the changes in clinicians' awareness over time and of the fact that the diagnostic methods have evolved during the last decades.

The patients with HFpEF represent about a half or even more of the patients with heart failure and the prevalence of HFpEF is on the rise [4-8]. HFpEF is mainly a disease of the elderly, who associate numerous cardiovascular and non-cardiovascular comorbidities [9].

HFpEF is more prevalent in women than in men, with a ratio women to men of 2:1, explained by the different sex cardiomyocite remodeling pattern in women than men [10,11]. In men, the eccentric left ventricle remodeling is more frequent, while in women the concentric remodeling is more frequent, as a response to aortic stenosis or hypertension [10]. Due to the concentric remodeling, women have a smaller left ventricle cavity and an increased wall thickness, with less collagen deposition [10]. Consequently, women have a better contractility and ejection fraction of the left ventricle, with the predominance of HFpEF. Women with HFpEF are more likely to be obese, hypertensive or to have renal disease or diabetes mellitus, while men are more likely to have coronary artery disease, atrial fibrillation, chronic obstructive pulmonary disease, anemia [12]. Even if HFpEF is more common in women, they have a better prognosis, with a rate of hospitalization with 20% less than men and a lower risk of cardiovascular and non-cardiovascular events. [12]

RISK FACTORS

Traditional cardiovascular risk factors, such as smoking, obesity, diabetes mellitus, hypertension, precede the onset of both heart failure with reduced and preserved ejection fraction, but there are specific risk factors for each of them. While male sex, myocardial infarction, left bundle branch block or high potassium level represent major risk factors for HFrEF, the risk factors for HFpEF are female sex, higher systolic blood pressure, right bundle branch block and atrial fibrillation [13-15].

Hypertension is common in patients with HFpEF and increases the risk of developing heart failure. The optimal treatment of hypertension improves diastolic filling, leads to the regression of left ventricular hypertrophy and may reduce the progression of heart failure.

Atrial fibrillation (AF) and HFpEF are related, and each of the diseases predisposes to the other. AF occur in approximately two thirds of the patients with HFpEF and contribute to the progression of the illness, due to the uncontrolled ventricular rates and the loss of atrial contraction and its contribution to the left ventricle filling, leading to a shorter filling time and diastolic dysfunction of the left ventricle [16]. When present together, HFpEF and AF lead to a worse outcome than each condition separately [17]. Patients with HFpEF and AF have a higher risk of stroke and mortality. All patients with HFpEF and AF should receive an oral anticoagulant and should have a good control of the ventricular rate.

Myocardial ischemia may contribute to HFpEF, too, by altering the diastolic filling. Significant coronary artery disease is present in more than half of the patients with HFpEF. Patients with HFpEF and myocardial ischemia have a greater risk of ventricular dysfunction and mortality than those without myocardial ischemia. Coronary revascularization can improve the prognosis of patients with HFpEF and myocardial ischemia.

Regarding patients with diabetes mellitus, particularly patients with insulin-dependent diabetes mellitus have an increased risk to develop major adverse cardiovascular events, including cardiovascular mortality, hospitalization for heart failure, non-fatal myocardial infarction, non-fatal non-hemorrhagic stroke, aborted cardiac arrest. Therefore, patients with HFpEF and diabetes have a worse quality of life and poorer outcomes than those without diabetes mellitus.

Comorbidities such as obesity, diabetes mellitus, chronic kidney disease, anemia, chronic obstructive pulmonary disease, and obstructive sleep apnea are related to the worsening of heart function in HFpEF. The treatment of these comorbidities improves the prognosis of heart failure and reduces mortality [18-20].

PATHOPHYSIOLOGY OF HEART FAILURE WITH PRESERVED EJECTION FRACTION

HFpEF is characterized by a normal systolic function, but abnormal diastolic function, with inappropriate filling of the left ventricle in the presence of normal pressure, initially. In more advanced stages, it associates also elevated filling pressures, especially during physical exercise. High filling pressures are considered the primordial cause of dyspnea and exercise intolerance [21]. The abnormalities encountered in HFpEF include delayed relaxation, stiffening of the myocardium and inappropriate filling dynamics.

The changes that occur in the cardiomyocites are the key to understand the dysfunction that appears in HFpEF and consequently to discover a specific treatment. An important element is cardiac hypertrophy. The extent of hypertrophy is a major predictor for HFpEF outcome. Other elements that contribute to HFpEF are fibrosis, left ventricle filling pressure, left ventricle end-diastolic volume, systemic inflammation, and metabolic disorders [22].

HFrEF is characterized by a diminished contractile response of the cardiomyocite, reduced availability of calcium activator and inadequate storage of calcium in the sarcoplasmic reticulum [22]. Knowing these mechanisms, HFrEF may benefit of a specific treatment which acts at the level of renin-angiotensin-aldosterone system and beta-adrenergic receptors. The treatment for HFrEF is ineffective in HFpEF, because of the different pathophysiological mechanisms.

In the case of HFpEF, there are no animal models, which is a major problem to a complete understanding of the pathophysiological mechanisms, in order to establish a specific therapy.

A study published in June 2018 suggests a new theory regarding HFpEF: hypertrophic cardiomyocytes develop also hyperfunction and elevated availability of systolic calcium activator [23]. In vivo, it is present a diastolic dysfunction and in vitro, hypercontractility of the cardiomyocytes. The researchers also noticed discrete, focal areas of fibrosis and in vivo, propensity to arrhythmias, caused by the instability of the calcium from the sarcoplasmic reticulum, and sudden death [23]. Apparently, the hypercontractility due to the increase of the L-type calcium channel density is responsible for the normal systolic function [23]. On the other hand, the high level of calcium limits the relaxation and promotes the stiffness of the ventricle walls. It was noticed also a deficit in cardiomyocytes, which leads to the compensatory hypertrophy of surviving myocytes [23]. Therefore, when failure occurs, diastolic dysfunction is predominant, but ejection fraction is preserved and end-diastolic volume is normal. There have been also observed the hypertrophy of the cardiomyocytes, the stiffness of the ventricle walls and focal interstitial fibrosis.

Arrhythmias can occur in HFpEF and they are related with the high levels of operational calcium, which confer instability, and with spontaneous release of calcium from the sarcoplasmic reticulum during diastole. Arrhythmias increase the risk of sudden cardiac death [23].

Myocardial fibrosis contributes to diastolic dysfunction. Patients with HFpEF have a profibrotic state. Fibrosis is organized in focal areas, observed especially near the interventricular septum. Fibrosis increases the stiffness of the walls. Collagen type I and III are elevated in HFpEF, collagenase and metalloproteinase-1 are reduced, but tissue inhibitor of matrix metalloproteinase-1 is increased, changes which contribute to fibrosis [23]. In tissue biopsy of patients with HFpEF, inflammatory cells have been also found. Hypertrophy is related to a diminished population of cardiomyocytes at an early-stage of growth. Hypercontractility predisposes to cardiomyocytes rupture and substitution with fibrotic tissue. Consequently, the integrity of the cardiac muscle is affected by focal fibrosis and the change of the ventricle geometry. In time, as the failure progresses, the diastolic function is totally compromised, but the systolic function, measured by the ejection fraction, is conserved [23].

Ventricular stiffening is associated with vascular stiffening in HFpEF. Vascular stiffening increases with age and is related to hypertension, chronic kidney disease, diabetes mellitus and obesity [24-26]. Vascular stiffening requires increased cardiac output to fill the rigid arteries that contributes to ventricular stiffening. Thus, ventricular-vascular stiffening is a common association in patients with HFpEF.

Inflammation has an important role in HFpEF. Comorbidities, such as renal disease, diabetes mellitus, may contribute to the proinflammatory state [27]. Several proinflammatory cytokines are increased in HFpEF, such as interleukin-6, tumor necrosis factor α, pentraxin 3 and soluble ST2 [27]. These patients have systemic inflammation and endothelial dysfunction, caused by the elevated expression of vascular cell adhesion molecules: VCAM-1, E-selectin, reactive oxygen species (ROS) [20]. The high level of ROS leads to the reduction of nitric oxide and consequently aggravates cardiomyocyte stiffness, hypertrophy and fibrosis [20,26].

DIAGNOSIS OF HFpEF

Heart failure can be initially suspected based on clinical criteria. For a definite diagnosis, it is mandatory to perform an echocardiography.

At echocardiography, the ejection fraction of the left ventricle, the thickness of the ventricular walls, the cavities' geometry and dimensions, the associated pathologies, such as valvular stenosis or insufficiency, are evaluated.

The clinical and paraclinical elements necessary for the diagnosis of HFpEF/HFmrEF are:

- The presence of symptoms and signs of heart failure.
- A left ventricle ejection fraction ≥ 50% for HFpEF and 40-49% for HFmrEF.
- Increased levels of natriuretic peptides: BNP > 35 pg/mL; NT-proBNP > 125 pg/mL.
- Objective elements of structural and/or functional disorders of the heart as a possible cause for the clinical presentation.
- If the diagnosis is uncertain, a stress test or invasive measurement of increased left ventricle filling pressure may be necessary [1].

The specific symptoms of heart failure are breathlessness at variable degrees of effort or at rest and exercise intolerance. Dyspnea interferes with the daily activities and impairs the quality of life. On physical examination, patients with heart failure have pulmonary crackles, bilateral ankle edema, jugular venous dilatation, laterally displaced apical beat.

Echocardiography is the conclusive method for the diagnosis of heart failure. The left ventricle ejection fraction (LVEF) is the most important parameter used to determine the systolic function of the left ventricle and a powerful predictor of death in patients with reduced ejection fraction [27]. LVEF is an important predictor for fatal and nonfatal cardiovascular events in patients with heart failure, including heart failure-related death, sudden cardiac death, hospitalization, myocardial infarction, especially in patients with reduced ejection fraction [28]. A 10% reduction of the ejection fraction is associated with a 39% higher risk of cardiovascular mortality [27].

In patients with HFpEF, echocardiography reveals a normal or near-normal ejection fraction and inadequate diastolic relaxation and left ventricle filling.

The structural elements of HFpEF are the left atrial volume index > 34 mL/m^2, a left ventricular mass index ≥ 115 g/m^2 for males and ≥ 95 g/m^2 for females [1].

The diastolic dysfunction has 3 stages that can be evaluated by echocardiography. The first stage is delayed relaxation, with an E/A ratio under 0.8, deceleration time of E wave > 200 ms, E/e' medium ratio less than 8. The second stage is pseudonormal function, with E/A ratio between 0.8 and 1.5, deceleration time of E wave between 160 ms and 200 ms, E/e' medium ratio between 9 and 12. The last stage is the restrictive pattern, with E/A ratio more than 2, deceleration time of E wave less than 160 ms, E/e' medium ratio more than 13 [28].

If echocardiography at rest is inconclusive, the diastolic stress test, using a semi-supine bicycle to measure the pulmonary artery pressures and cardiac output changes with exercise, may be necessary [1]. Another paraclinical test is invasive measurement of the filling pressures – the pulmonary capillary wedge pressure ≥ 15 mmHg, left ventricular end-diastolic pressure ≥ 16 mmHg [1].

In the presence of atrial fibrillation, the echocardiographic diagnosis of HFpEF is more difficult, because the left atrial volume index is higher, the functional parameters of diastolic disorder are not well established. Also, the values of natriuretic peptides are higher in patients with atrial fibrillation. On the other hand, atrial fibrillation can be a mark of HFpEF. Patients with HFpEF and atrial fibrillation may have more advanced heart failure than those with HFpEF and sinus rhythm [1].

Biomarkers measured with highly specific and sensitive assay play an important role in the diagnosis of heart failure and its risk stratification [27]. The Brain Natriuretic Peptide (BNP) is higher in patients with HFpEF than in patients without heart failure, but lower than in patients with HFrEF [28]. BNP is associated with diastolic left ventricle walls stress and pressure. Biomarkers of extracellular matrix and fibrosis (soluble ST2, galectin-3, type I procollagen C-terminal propeptide, type I and II collagen amino-terminal propeptide, collagen telopeptides, matrix metalloproteinases – MMP-1, MMP-2, MMP-8, MMP-9, tissue inhibitor of metalloproteinases – TIMP-1, TIMP-4, osteopontin) can be increased in patients with HFpEF [6]. Renal biomarkers, such as cystatin C and urinary albumin, and cardiac troponins are also elevated6. All these biomarkers may sustain the diagnosis of HFpEF, but have a poor prognostic role and, excepting natriuretic peptides, cannot be used to guide the treatment [6]. The natriuretic peptides values are related to the severity of the disease, therefore higher levels of natriuretic peptides are linked with more advanced HFpEF [6].

TREATMENT OF HFpEF

There is no specific or effective treatment for patients with HFpEF, in order to reduce the mortality rate [29]. In clinical practice, fewer patients with HFpEF appear to receive beta-blockers, diuretics, angiotensin-converting enzyme inhibitors, angiotension receptor blockers and aldosterone antagonists than patients with HFrEF and if they receive these drugs, it may be to treat comorbidities, such as hypertension, coronary artery disease, atrial fibrillation [29,30].

Renin-angiotensin-aldosterone system blockers have been studied in patients with HFpEF, due to their effects on hypertension, fluid retention and fibrosis. Also, beta-adrenergic blockers were studied due to their effects of prolonging diastole and increasing the filling time of the left ventricle. Despite their well-known benefits in patients with HFrEF, in those with

HFpEF beta blockers offer only a modest symptomatic improvement and do not reduce mortality [31,32]. Some studies revealed a decreased hospitalization rate with angiotensin converting enzyme inhibitors/ angiotensin receptors blockers [6]. The study „The Effects of Candesartan in Patients with Heart Failure and Preserved Left-Ventricular Ejection Fraction" concluded that patients with HfpEF who received candesartan had fewer hospitalizations for decompensated heart failure compared with placebo, but without influence on the mortality rate [6]. Probably, renin-angiotensin-aldosterone-system does not have such an important role in HFpEF as in HFrEF, this is why its blockers have much less benefits [6].

The use of aldosterone antagonists was also tested in HFpEF. The results of the study ALDO-DHF, published in 2013, showed an improvement of the diastolic function, but no improvement was noticed in the maximal exercise capacity, clinical symptoms and quality of life [6]. The TOPCAT study, whose results have been published in 2014, also did not achieve its primary outcomes – cardiovascular mortality or aborted cardiac arrest, only a small decline in hospitalization rate has been observed [6,33].

Sildenafil, a phosphodiesterase-5 inhibitor, was tested in RELAX study and showed no advantage on mortality or symptomatic relief [6].

Statins can be prescribed in patients with HFpEF and have shown a significant impact on survival, due to their pleomorphic anti-inflammatory effects [6].

Considering the lack of results on mortality rate with beta-blockers use, ivabradine was also studied. Ivabradine slows the sinus node rate, but does not affect contractility and peripheral vasculature, in contrast to beta-adrenergic blockers [6]. Studies on mice revealed an improvement in the left ventricle function and lowering of aortic stiffness and fibrosis after four weeks of therapy with ivabradine [6]. A clinical trial, including 61 patients with HFpEF, has found an improvement in exercise capacity and decreased exercise-induced E/e' ratio, which represents diastolic pressure index, with ivabradine versus placebo [6]. No side effects appeared. Ivabradine cannot be used in patients with bradycardia or chronotropic incompetence and neither in patients with restrictive type of diastolic disorder, because filling occurs early and rapidly in these patients and decreasing heart rate would worsen cardiac output even more [6].

Introduction of device therapy was a great progress for patients with HFrEF, with pacemakers, implantable cardioverter defibrillators, and resynchronization therapy. In patients with HFpEF, asynchrony is rarer than in HFrEF, thus device therapy has no applicability in HFpEF [6].

No treatment has yet been found to diminish morbidity and mortality in patients with HFpEF and HFmrEF. An important objective of the treatment in these patients is to improve symptoms and the quality of life. Diuretics are prescribed to reduce pulmonary and systemic congestion signs and symptoms. As mentioned before, aldosterone antagonists and beta-blockers do not improve symptoms in patients with HFpEF, only a relative improvement in NYHA class with candesartan was observed [1].

Regarding hospital admission, patients with HFpEFin sinus rhythm may benefit from the use of nebivolol, spironolactone and candesartan, which decrease hospital admission1. For patients who associate atrial fibrillation, beta-blockers are ineffective and digoxin has not yet been studied [1].

Arterial hypertension should be carefully treated in patients with HFpEF/HFmrEF, who have often systolic arterial hypertension. The antihypertensive drugs recommended are diuretics, angiotensin-converting enzyme inhibitors, angiotensin receptor blockers and aldosterone antagonists [1]. Beta-blockers appear to be less effective [1].

The specific therapy for comorbidities is also important, for example losing weight in obese patients, oral anticoagulants for atrial fibrillation or other arrhythmias, medical and/or interventional treatment for coronary artery disease, treatment of diabetes mellitus, preferably with metformin [1], renal disease treatment [34-37], treatment of anemia, chronic obstructive pulmonary disease and obstructive sleep apnea.

The most challenging situation is the treatment of HFpEF when different kinds of surgical procedures are required [38-40]. Either is abdominal surgery [41-44] or pelvic interventions [45-47], in males [48-51] or females procedures [52-55], the management of these comorbidities involves complex treatment strategies from surgeons, cardiologists or anesthesiologist.

Thus, the management of HFpEF includes diuretics, which reduce systemic congestion and improve the filling pressure of the left ventricle, and treatment of comorbidities, which improves considerably the clinical outcome [56].

PROGNOSIS OF PATIENTS WITH HFpEF

Overall, the prognosis of patients with HFpEF is similar with those with HfrEF [57]. Patients with HFpEF have more frequent a non-cardiovascular cause of death or hospitalization, in contrast to the patients with HFrEF, who have commonly a cardiovascular cause for hospitalization or death [1]. Renal involvement in patients with HF is a redutable complication, especially in patients with increased blood pressure [58-61].

The left ventricle hypertrophy and elevated left ventricle filling pressure correlate with hospitallizations for heart failure [62,63]. Recurrent hospitalizations are as frequent in HFpEF as in HFrEF and are associated with higher mortality rate [62].

There are sex-related differences between the risk factors for HFpEF. Hypertension, obesity and renal disease are more common in women, while ischemia, atrial fibrillation, chronic obstructive pulmonary disease and anemia are more frequent in males [12]. Women have a 20% lower risk of hospital admission than men, and also a lower risk of cardiovascular and non-cardiovascular events [12]. Women have an overall better prognosis than men [12]. The prognosis is modified by the presence of atrial fibrillation, stable angina pectoris, and renal disease in both sexes [12].

CONCLUSIONS

Patients with heart failure with preserved/mid-range ejection fraction represent approximately a half of the patients with heart failure.

The diagnosis of HfpEF is based on clinical signs and symptoms, echocardiography, natriuretic peptides levels and stress tests or invasive measurement of filling pressures and left ventricular end-diastolic pressure, if necessary.

Overall, the prognosis of patients with HFpEF is similar with those with HFrEF, with the difference that in these patients the death of non-cardiovascular cause is more common, in contrast to the patients with HFrEF, in whom the cardiovascular death is more frequent.

There has not yet been found a specific therapy for HFpEF that may reduce morbidity and mortality, in contrast to HFrEF. The main objective of the treatment in patients with HFpEF is to improve clinical status and decrease hospitalizations.

Further studies are needed to establish an effective treatment, to increase survival in these patients. In conclusion, HFpEF continues to be a challenge for clinicians regarding the optimal treatment.

ORIGINAL ARTICLE

High values of procalcitonin in non-septic patients with thermal and airway burns – an early severity predictor?

Bogdan I. Pavel[1,2], Luisa M.V. Vătășoiu[1], Adrian T. Stanculea[1], Adina M. Milos[1], Alina A. Pastrav[1], Adrian E.I. Roșca[2], Ana-Maria S. Zăgrean[2], Adrian M.E. Otoiu[3], Mihaela A. Covrig[3], Ileana C.P.V. Boiangiu[1]

Abstract: *Purpose – Combined airway burns with cutaneous burns is a further negative prognostic factor in burn patients. In this study we tried to identify the most relevant negative prognostic factors at admission in a relatively homogeneous population.*

Methods – In this study, ten young patients who suffered from skin and airway burns following a fire in a club, admitted to our ICU department, were included. At the intake, ABSI and APACHE II scores were calculated, and a series of biomarkers were also collected. The correlation and associations between gravity scores and biomarkers was then calculated using the Spearman correlation and Chi square tests.

Results – Based on data analysis, we found very high values of ABSI 8.9 ± 1.4 and APACHE II 25.4 ± 2.79 scores, procalcitonin (46.16 ± 68.18 ng/ml), white blood cells (41.26 ± 15.66 × 103/mm3), hematocrit (51.6 ± 7.31 %), and low corrected albumin values (22.08 ± 4.66 g/l). The statistical analysis revealed a good correlation between gravity scores and values of PCT and low albumin levels ($p< 0.05$). The mortality was also associated with the need for vasopressor support from the beginning ($p < 0.05$).

Conclusions – Adverse prognostic factors that we have identified in this group of young patients with skin burns and airway include: increased values of the severity scores and PCT, low values of corrected albumin and vasopressor support necessary at admission.

INTRODUCTION

Burns represent one of the most aggressive injuries of the human body known for high mortality, thus raising major public health issues such as increased length of hospitalization and recuperation, along with psychological and physiological traumas, all these leading to increased costs [1-4].

Burns-induced mortality rate is globally increased, and surprisingly high in the developing countries, including Europe's burn centers, where it ranges between 1.4% and 18% [5]. The high mortality is associated with a number of factors, including long-term severity of burn driven inflammatory response of the host, secondary human body frailty and abnormal response to further injuries like sepsis [6, 7]. The association of airways' and cutaneous burns induces a supplemental increase of the inflammatory response, difficult to quantify because of the inaccurate evaluation of the burns from the surface of the lungs and burn degree same time [8]. Consequently, in the case of mixed cutaneous-and-airway burns the mortality increases,

despite the usage of advanced techniques to support lung function (Extracorporeal membrane oxygenation – ECMO) [9-12]. On the other hand, in the beginning, it is unclear whether a patient has both cutaneous and airway burns, as for the latter it might take up to 48 hours to observe any clinical manifestations. As such, the airways' burns assumption is made based on anamnesis and correlation between the high incidence of airways burns and the increased surface of cutaneous burns [11]. If one can clinically suppose an airways burn (in this case a bronchoscopy is usually performed for a certain diagnosis), there is no toll to quantify its' impact on the inflammatory response of human body. Currently, there is just an indirect estimation of their aggression on the human body using either dedicated markers or severity scores. Despite the wide availability of severity scores as Acute Physiology And Chronic Health Evaluation (APACHE II and APACHE III), Abbreviated Burn Severity Index (ABSI), and biomarkers (such as microalbuminuria, serum albumin, C-reactive protein, procalcitonin (PCT)), both used to estimate the severity of cutaneous burn injuries, they are not sufficiently standardized for the estimation of mortality risk in case of combined thermal and airway burns [13-16].

Considering the increased mortality and likeliness of combined burns complications, it is paramount to know the severity degree and the prognosis of the burn evolution from the beginning.

In the current study, we evaluated the absolute values of serological markers and severity scores upon admission to the Intensive Care Unit (ICU) in a group of young adult patients who presented both cutaneous and airway burns following the fire in a club in Bucharest, Romania and we studied their correlation with mortality.

MATERIAL AND METHOD

This study includes the victims of a fire at a club in Bucharest, in the night of 29-30 October 2015, all of them hospitalized that night in the Intensive Care Unit of the Emergency Hospital for Plastic Reconstructive Surgery and Burns, in Bucharest. All admitted patients underwent surgery (non-excisional debridement) and subsequently, they were connected to artificial breathing devices, central venous and urinary catheters being placed on them too.

Hydroelectrolytic rebalancing started from the operating room with a crystalloid solution (Ringer lactate), following the Parkland protocol (4 ml/kgc/Total Burn Surface Area-TBSA), while in patients who could not maintain a Mean Arterial Pressure (MAP) > 65 mmHg, epinephrine was administered in continuous perfusion from the beginning. Patients were admitted to ICU between 00:00 and 03:00 on 30 October, and the first set of blood tests was harvested at 6:00 on 30 October. To determine the quantitative procalcitonin (PCT) values, the testers arrived after about 48 hours from admission.

We estimated the severity of the patients' burns using ABSI and APACHE II scores.

In, order to estimate the appropriate level of serum albumin under hypovolemic conditions, we corrected it in accordance to the hematocrit (Ht) level, using the following formula:

$$corrected\ albumin\ level\ = measured\ albumin\ level\ \times \frac{normal\ Ht}{measured\ Ht}$$

where normal hematocrit (Ht) is 45% for men and 40% for women.

For the determination of the blood cells count, the Ac-T 5 diff CP (Beckman Coulter, Germany) was used. The biochemical markers were measured using the Konelab-20i/20XTI (Thermo Electron Corporation, Finland). Coagulation parameters were determined using the ACL-7000 instrument (Instruments Laboratory, Italy). PCT was assessed using the VIDAS, bio Merieux VITEK, France.

The conduct of this study was approved by the Ethics Committee of the Emergency Hospital for Plastic Reconstructive Surgery and Burns (number 5/10 July 2017).

Statistical analysis

The data is presented as the average ± standard deviation for quantitative variables, and absolute frequencies and relative frequencies, respectively for the qualitative variables. Batch variance analysis was performed with the Levene test. For the analysis of the difference between the environments the t-student test was used together with the calculation of the confidence intervals. For the correlation analysis Spearman correlation coefficient and chi-square nonparametric test were employed. In addition, for the correlation analysis we performed Percentile Bootstrap Correlation in order to calculate the Pearson parametric correlation coefficient. Confidence intervals for the value of the t test and the Pearson correlation coefficient were obtained through the bootstrap method with 10,000 and 1,000 replications, respectively. The results were considered statistically significant for a p value <0.05. For the statistical analysis IBM SPSS 18.0 and several R packages, such as wBoot, were used.

RESULTS

During the night of 29-30 October 2015, ten patients (seven male and three women) were admitted in our ICU. The deep cutaneous burn lesions (3rd degree) ranged between 5% and 50% of the body surface area and the age range of admitted patients was 18 to 40 years old. Their ABSI scores were between 7 and 11, associating a mortality between 10% and 60 - 80% and the APACHE II score ranged between 23 and 30, which is associated with a 46% to 70.3% mortality at admission. In Table 1 we report demographical data, several laboratory measures describing the admission conditions and, for some of them, the measures sampled 30 hours after admission.

Table 1. Characteristics of the patients included in the study

	Values
WBC (1000/ml)	41.26 ± 15.66
PLT (1000/ml)	142.5 ± 50
APTT (sec)	40.27 ± 10.76
INR	1.87 ± 0.45
pH	7.04 ± 0.11
Temperature (^{0}C)	35.95 ± 0.61
Albumin (g/l)	25.95 ± 4.52
Corrected Albumin (g/l)	22.08 ± 4.66
PCT (ng/dl)	46.16 ± 68.18
Creatinine (mg/dl)	1.39 ± 0.53
TGO (mg/dl)	70.8 ± 38.31
TGP (mg/dl)	54 ± 43.28
One month mortality (%)	80%
One year mortality (%)	90%
WBC (1000/ml)	41.26 ± 15.66
PLT (1000/ml)	142.5 ± 50
APTT (sec)	40.27 ± 10.76
INR	1.87 ± 0.45
pH	7.04 ± 0.11
Temperature (^{0}C)	35.95 ± 0.61
Albumin (g/l)	25.95 ± 4.52

Note: TBSA III = Total Burn Surface Area 3rd degree, WBC = white blood cells, PLT = platelets, APTT = activated partial thromboplastin time, INR = international normalized ratio, Corrected Albumin represents corrected values of albumin according to hematocrit, PCT = procalcitonin, TGO = glutamic oxaloacetic transaminase, TGP = glutamate-pyruvate transaminase.

For these variables, the values presented are mean ± standard deviation. Gender distribution and mortality after one month and one year are also provided in Table 1. Blood tests revealed: high levels of white blood cells (WBC) of 41.26 ± 15.66/mm3, elevated hematocrit (Ht) level51.6 ± 7.31%, albumin values of 25.95 ± 4.52 g/dl (uncorrected) and 22.08 ± 4.66 g/dl (corrected), creatinine level of 1.39 ± 0.53 mg/dl, glutamic oxaloacetic transaminase (TGO) values of 70.8 ± 38.31 mg/dl and glutamate-pyruvate transaminase (TGP) levels of 54 ± 43.28 mg/dl.

Forty-eight hour procalcitonin (PCT) values were extremely elevated: 49.85 ± 67.34 ng/ml (PCT was measured in eight patients). The coagulation parameters activated partial thromboplastin time (APTT), international normalized ratio (INR), and platelets (PLT) we report in Table 1 were measured at 30 hours from admission (the second set of analysis) because at the first set there were no changes (first set: APTT = 29.3 ± 3.01, INR = 1.15 ± 0.18, PLT = 306.2 ± 108.47). So we found: APTT = 40.27 ± 10.76 seconds, INR = 1.87 ± 0.45, PLT = 142.5 ± 50*103/ml. The pH values of 7.04 ± 0.11 presented in the table were obtained from central venous blood samples after the central venous catheters were placed. The temperature at admission had a mean value of 35.95 ± 0.61 Celsius degrees. Of the ten patients in ICU eight needed vasopressor support at admission and also during the next days.

Table 2 presents values of serological markers, Total Burn Surface Area 3rd degree in terms of mean ± standard deviation, and the number of patients who required vasopressor support with epinephrine (norepinephrine from the second day) from the admission, considering the total study group and the subgroup of those who did not survived.

Table 2. Values of serological markers, total burn surface area (TBSA) and norepinephrine status in the study group and subgroup

	Total	Non Survivors	p value
Albumin (g/l)	25.95 ± 4.52	24.63 ± 3.97	0.26
Corrected Albumin (g/l)	22.08 ± 4.66	21.25 ± 4.62	0.35
PCT (ng/ml)	46.16 ± 68.18	65.88 ± 71.52	0.35
Hematocrit (%)	51.6 ± 7.31	51.19 ± 5.07	0.43
WBC (1000/ml)	41.26 ± 15.66	44.00 ± 16.22	0.36
Norepinephrine	8 (10)	8	0.03
TBSA III (%)	25.7 ± 16.73	29.62 ± 16.27	0.30

Note: WBC = white blood cells, PCT = procalcitonin, Corrected Albumin represents corrected values of albumin according to hematocrit. TBSA III = Total Burn Surface Area 3rd degree. Data are presented as mean ± standard deviation.

In the case of norepinephrine requirements association chi-square test were performed.

Statistical significance is considered for a p value < 0.05. We performed parametric t-tests for the above variables in order to assess whether there are sizeable differences between the values recorded for all patients versus the values for those that died. Due to the existence of abnormal values for TBSA and PCT 48 hrs, we have eliminated TBSA values exceeding 8, and PCT 48H values under 200. Table 3 presents two versions of the t-tests: regular tests assuming unequal variances, and bootstrap tests with 10000 replications.

Table 3. T-tests and bootstrap confidence intervals

Parameter	T-test value	P-value	Bootstrap confidence interval limits			
			Lower 95%	Upper 95%	Lower 90%	Upper 90%
Corrected albumin	0.37421	0.7134	-2.90235	4.7619	-2.52655	4.1034
TBSA	-0.50211	0.6227	-17.32	9.86	-2.3798	4.0939
PCT	-0.38325	0.7093	-105.1441	8.8855	-100.0322	5.32
WCB (divided by 100)	-0.36157	0.7228	-16.404	8.845175	-13.9097	7.57075
TBSA>8	-0.28615	0.7793	-15.71875	11.5	-13.75	9.25
PCT48h <200	-0.4898	0.6367	-37.916	19.39814	-32.02486	14.458
Albumin	0.65438	0.5223	-2.195	4.57	-1.575	4.21
Hematocrit	0.16848	0.8683	-4.50495	5.85595	-3.6257	5.1709

All results show that differences between the two samples are non-significant at 90% confidence level. Further, we investigated the correlations between severity scores (ABSI and APACHE II), procalcitonin (PCT) and corrected albumin using the Spearman non-parametric (rank) correlation coefficient. Table 4 shows that these correlations are significant at 10% significance level. We pursued a more in-depth analysis of the correlations between the above variables calculating the Pearson parametric correlation coefficient using the Percentile Bootstrap Correlation Method available in the package wBoot of R. intervals obtained after 1000 replications.

Table 4. Spearman correlations

Correlation	Correlation Coefficient	p value
ABSI - APACHE II	0.54	0.053
APACHE II - Corrected Albumin	-0.59	0.036
ABSI - PCT	0.73	0.019
APACHE II - PCT	0.73	0.019

Table 5 presents the values of the correlation coefficient, the standard error as well as the 90% or 95% confidence

Table 5. Pearson correlations: results from the Percentile Bootstrap Correlation Method, 1000 replications

Variables	Mean coefficient	Standard error	Confidence interval		
			Lower Limit	Upper Limit	Level
ABSI , Apache II	0.4904211	0.2582198	0.008991	0.8477	90%
ABSI , PCT	0.5594826	0.1655465	0.2769	0.8614	95%
Apache II, PCT	0.5487429	0.208531	0.1969	0.9677	95%
Apache II, Corrected Albumin	-0.5645653	0.2334818	-0.8677	-0.151	90%

Bronchoscopic aspects at 48 hours did not reveal severe changes, most of them related to mild or moderate impairment of the lungs (Grade 0-2), only one exception with severe lesions (Grade 3) being identified. Following the Berlin criteria for the classification of acute respiratory distress syndrome (ARDS), nine patients presented mild ARDS and only one moderate ARDS upon admission to ICU.

We have obtained a good correlation between the APACHE II score at admission and the procalcitonin values (at 48 hours), ABSI score and procalcitonin and also between the

APACHE II score and albumin (Table 3).

One month after admission, two of the ten patients survived and after one year, one patient survived.

DISCUSSION

Upon arrival, patients showed signs of increased burn severity including high values of PCT (at 48 hours from admission), WBC, APACHE II & ABSI scores, and Ht, as well as low levels of albumin. Eight of the ten admitted patients required vasopressor support from the beginning.

It is known that PCT, a molecule secreted by the thyroid, intestine, liver, kidney, muscle and adipocytes under the action of TNFα and IL-1β has elevated values especially in bacterial sepsis [17] and not in viral infections [18] and also has a rapid kinetic growth from the first few hours of injury to a maximum of 12 hours [19]. PCT is also increased in septic burned patients. Several studies were performed for identifying a cut-off value for sepsis in burned patients, the yielded values ranging from 0.5 ng/ml to 1.5 ng/ml [20-23]. The highest PCT values reported for non septic patients were 2.3 ± 3.7 ng/ml [20].

Nevertheless, PCT was also found to be increased in non-septic states by systemic inflammatory response syndrome-SIRS, which is logical considering that its secretion is stimulated by TNFα and IL-1β. Additionally, it has been noticed that in complex visceral liver/spleen plus thoracic trauma the PCT values go up to 9.37 ± 2.71 ng/ml [24], consequently elevated values were also found in other SIRS states [25, 26]. In burns it was found that PCT grows even in the absence of infection, so patients who associate PCT values > 2 ng/ml within the first 48 hours of admission have a mortality of 65% at 50 days [27]. According to the American Burns Association criteria (ABA) [28], we had just one patient who presented sepsis criteria in the first 48 hours, so the high PCT values observed in our patients (46.16 ± 68.18 ng/ml) were explained by an extremely aggressive inflammatory response to burn. Our opinion is that this reaction was induced not only by skin burns but also by pulmonary injury so that high PTC values on admission may also indicate an associated airway burn in patients who have such a suspicion.

Serum albumin is a marker of severity in critical patients and is associated with an increased mortality [29, 30]. Low levels of serum albumin and urinary albumin occur by increasing vascular permeability induced by pro-inflammatory mediators in SIRS or sepsis [31, 32]. Patients with burn injuries lose their albumin by increasing the capillary permeability induced by pro-inflammatory mediators and the serum albumin value correlates with the burned surface, so at a burned surface of 60%, serum albumin (at admission) is around 1.95 ± 0.02 g/l [33, 34, 35]. In a recent study, it was found that in patients with burn driven injuries an albumin value < 2 g/l is correlated with a mortality > 80% [36]. For our patients, the value of serum albumin on admission was 25.95 ± 4.52 g/dl and corrected albumin was 22.08 ± 4.66 g/dl. We consider it more useful to report corrected albumin values considering that patients have high hematocrit variations as most of them are hemoconcentrated at admission. In all of the studies we considered, the serum albumin values were presented without being adjusted to the hematocrit value.

The APACHE II score is known as a severity score that is used to estimate mortality in intensive care units [37]. Its correlation with mortality is applicable to burn patients [38, 39] and also to acute respiratory distress syndrome (ARDS) patients [40, 41]. In our group, the high APACHE II scores have been interpreted as being induced by an extreme inflammatory response probably induced by thermal and airway burns. The ABSI score is a good indicator of the severity of a thermal injury and seems to estimate quite well the burning severity in patients with airway burns [42, 43]. ABSI score has a similar prognostic value compared to APACHE II in estimating the severity of patients with both cutaneous and airway burns. ABSI and APACHE II predict a similar mortality and the correlation of their scores is at the p = 0.05 limit. In our patients, the WBC count at admission was extremely high 41.26 ± 15.66 *103/ml. These elevated values can be only partially explained by hemoconcentration because the mean value of the hematocrit was just slightly elevated. WBC count is also increased in other situations with a systemic inflammatory response but not to those values reported in our group [44, 45].

The mean serum creatinine value, at 6 hours after admission, was 1.39 mg/dl, which may be due to hypovolemia induced by renal hypoperfusion. On the other hand, elevated transaminases with predominantly TGO/TGP increased ratio may be explained by their release from the burn cutaneous area rather than by hepatic hypoperfusion. The triad: acidosis, hypothermia and coagulopathy has a poor prognosis in polytraumatized patients and in burn patients [46]. This triad is particularly presents in patients with cutaneous and airway burns. All the patients with skin and airway burns showed severe metabolic acidosis at admission. Coagulopathy did not immediately appear but emerged in the next 30 hours. Hypothermia (temperature under 35.5°C degrees) was present in just two patients at admission, and the mean value was about 35.95 Celsius degrees. The absence of hypothermia can be explained by the very short time until the patients were brought to the hospital, the fire being located in a club in Bucharest, relatively close to the hospital. Thus, out of the three parameters of the triad, in our patients, only 2 of them were present.

These changes of PCT, WBC and high APACHE II and ABSI scores can be explained by an extreme inflammatory reaction or septic shock. This inflammatory reaction could be caused by thermal cutaneous lesions and/or airway burns. Although we found a good correlation between the APACHE II score & PCT & corrected albumin, and also between ABSI score & PCT, we did not find a statistically significant correlation between the burn lesions surface or depth and the biological parameters. So we can state that the inflammatory reaction was determined by a mixed cause represented by the thermal cutaneous lesions and airway burns. For patients with airway burns, the etiology may be thermal or chemical. In most of our cases, bronchoscopy did not reveal significant structural changes in the upper airways, which led us to the idea that pulmonary injury was mixed, thermal and chemical. Although we did not obtain statistically significant changes, we found an increase in WBC, PCT and TBSA III values in the case of non-survivors compared to the mean values obtained in the entire group of patients. Yet, a statistically significant difference was obtained with regard to vasopressor support, so all eight patients requiring vasopressor support at the admission died in the first month.

The patients who survived one month from the incident, had PCT values at 48 hours of 3.14 ng/ml and 0.41 ng/ml, respectively, corrected albumin of 22.3 g/l and 28.45 g/l, respectively, while the APACHE II values were 24 and 23 respectively, and ABSI scores were 8 and 7 respectively. These were also the only patients who did not require vasopressor support at admission.

CONCLUSIONS

The association of airway burns to the cutaneous thermal lesions is linked to an increased mortality even in young patients. There is no dedicated marker or score for the assessment of the combined cutaneous and airways burns aggression on the human body but an association of markers and scores could improve the evaluation of the burn severity. The negative prognostic factors we identified in our group were high PCT values at 48 hours, low corrected albumin levels, vasopressor requirements and elevated APACHE II and ABSI scores. The WBC count and TBSA could be also considered in establishing the severity of the cases.

REVIEW ARTICLE

Article received on April 21, 2017 and accepted for publishing on September 18, 2017.

Hyphema – from the effect to the cause

Raluca D. Georgescu[1], Ovidiu Mușat[1], Corina Cernat[1], Diana Colța[1], Ana M. Boariu[1], Ioana Popescu[1], Tatiana Tănase[1], Lucian Alexandru[1]

Abstract: *The purpose of this review is to describe the etiology (traumatic, iatrogenic, spontaneous causes), clinical and paraclinical findings and the management of hyphemas.*

The clinical appearance of hyphema is variable and is influenced by the volume of blood and the amount of time erythrocytes are present in the anterior chamber. When hyphema is evident, a complete history should be obtained and a thorough physical examination performed to direct the initial selection of diagnostic tests. Secondary complications of hyphema include glaucoma, synechiae, cataract formation, blood-staining of the cornea, and blindness.

Early diagnosis and treatment can minimize or prevent the installation of secondary complications and improve the prognosis.

INTRODUCTION

Hyphema is blood collection in the anterior chamber of the eye (delimited anteriorly by the cornea, posteriorly by the lens and iris and circumferentially by the angle between iris and cornea).[1]

Depending on the blood volume present in the anterior chamber, hyphema is classified as (Figure 1):

- Grade 0: circulating erythrocytes (microhyphema)
- Grade 1: <1/3 anterior chamber volume
- Grade 2: 1/3 -1/2 anterior chamber volume
- Grade 3: >1/2 anterior chamber volume
- Grade 4: total anterior chamber volume (”eight ball hyphema”)

The symptoms that bring the patient to the doctor may vary depending of etiology, but the most common symptoms are blurred vision, pain and photophobia.

The most important thing in finding the etiology of hyphema is a detailed medical history of the patient. It’s important to ask the patient if he suffered a trauma, what was the mechanism and if an object was involved, because hyphema in some cases may be accompanied by the presence of an intraocular foreign body. Other questions will be related to certain diseases such as diabetes, sickle cell anemia or other blood disorders and treatment with antiplatelet agents or anticoagulants.

After a complete medical history, physical exam will include: biomicroscopy, FO exam, gonioscopy, ocular ultrasonography, ultrasound biomicroscopy, radiographic examination or CT (when there is severe orbit damage or the doctor suspects the presence of an intraocular

"eight ball hyphema"

ETIOLOGY

Most frequently hyphema is caused by trauma, followed by intraocular surgery and spontaneous hyphema: abnormal growth of blood vessels – neovascularization (diabetes, ischemia), intraocular tumors (iris melanoma, juvenile xanthogranuloma, retinoblastoma), infections (herpetic keratouveitis), blood dyscrasias (sickle cell anemia, leukemia), anticoagulant therapy.[4]

Traumatic hyphema is most common in young males. Ocular trauma may be blunt or lacerating. The mechanisms of developing traumatic hyphema are:

- In blunt trauma occurs a rapidly anteroposterior compression of the eye with equatorial expansion and increased intraocular pressure, which leads to shearing forces that tear the vessels of the iris and ciliary body with accumulation of red blood cells within the anterior chamber.

- In lacerating trauma, traumatic agent causes direct damage of the vessels

Studies have shown that more than 50% of the cases, hyphema occupies less than 1/3 of the anterior chamber volume and less than 10% of the cases hyphema occupies the total volume of the anterior chamber.

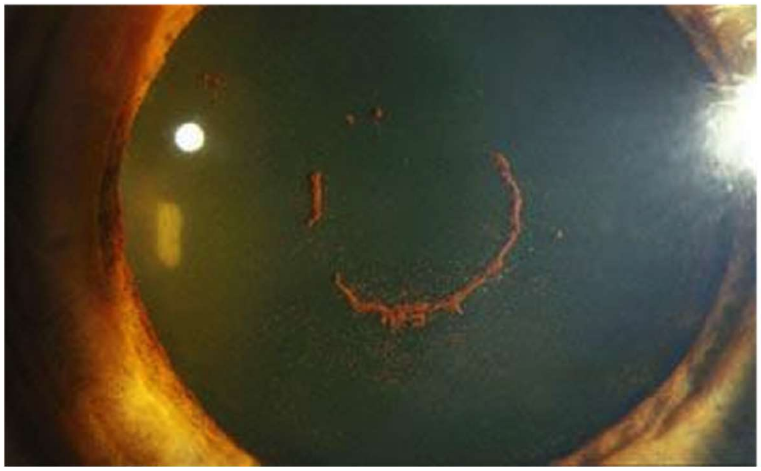
In the case of a trauma, hyphema may be accompanied by other injuries such as angle recession (seen in 85% of traumatic hyphemas and can be associated with the development of glaucoma), traumatic iritis (presence of inflammatory cells in the anterior chamber and presence of pigment on the anterior capsule – Vossius ring – Figure 2), fixed dilated pupil in approximately 10 % of the cases, iridodialysis (disinsertion of the iris from the scleral spur), cyclodialysis cleft (separation of the ciliary body from the scleral spur, creating a direct connection between the anterior chamber and the suprachoroidal space, leading to ocular hypotony), corneal changes (from minor abrasion to corneal endothelium damage), cataract, lens subluxation, posterior segment injuries (vitreous hemorrhage, retinal edema/hemorrhages/ holes/tears, choroidal rupture etc.).[1]

Hyphema caused by ocular surgery can occur both intraoperatively and postoperatively. Intraoperatively, has been described in cataract surgery by direct damage of iris vessels, in peripheral iridectomy, cyclodialysis, and intervention on the posterior pole. Amsler sign is the presence of blood in the anterior chamber in patients with Fuchs heterochromic cyclitis, following rapid pressure change after anterior chamber paracentesis.

Postoperatively, the Uveitis Glaucoma Hyphema syndrome may occur after cataract surgery, caused by mechanic trauma of the iris by the IOL, more common in anterior chamber IOL.[5]

Spontaneous hyphema may occur secondary to iris neovascularization (proliferative diabetic retinopathy, ocular ischemic syndrome, retinal vein occlusion, chronic choroidal detachment), chronic uveitis (herpes zoster), tumors (uveal melanoma, retinoblastoma, lymphoma, leukemia, metastasis etc.), drugs (both anticoagulant and antiplatelet agents), blood dyscrasias (hemophilia, thrombophilia, von Willebrand disease, immune thrombocytopenic purpura).[6,7]

Figure 2: Vossius ring [11]

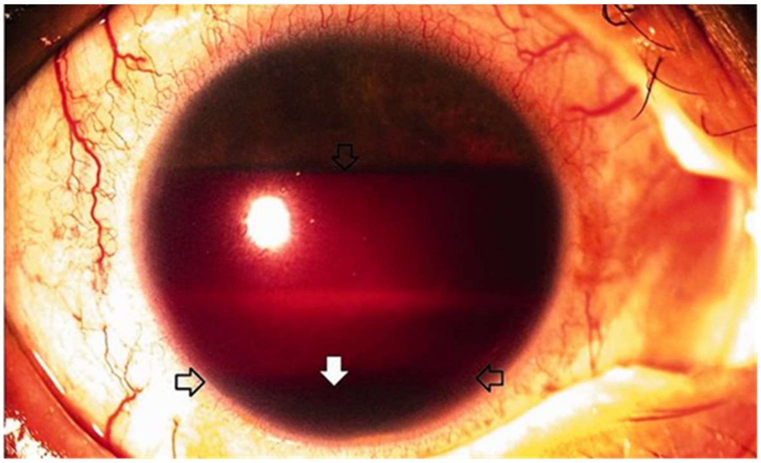


COMPLICATIONS

Obstruction of the trabecular meshwork with increased intraocular pressure is one of the complications that can result from untreated or improperly treated hyphema. This occurs in about 1/3 of hyphema cases. Studies have shown that 25% of patients develop intraocular pressure >25 mmHg and 10% of patients develop intraocular pressure > 10 mmHg. Usually, patients with a larger volume of blood in the anterior chamber have an increased risk in developing elevated intraocular pressure. Another risk factor would be the appearance of the recurrent bleeding. Intraocular pressure should be monitored daily. An untreated intraocular pressure > 35 mmHg for more than 5-7 days can lead to irreversible optic nerve damage.[8]

Recurrent bleeding or secondary hemorrhage (Figure 3) is another complication that can occur. It is described as increase of blood volume or appearance of a new layer of fresh blood in the anterior chamber. Most commonly occurs 3-5 days after the initial injury as a result of blood clot lysis. Recurrent bleeding increase the risk of other complications such as: increased intraocular pressure, corneal blood staining, optic atrophy, and peripheral anterior synechia. This complication is often associated with a weak prognosis or need for surgery.[9]

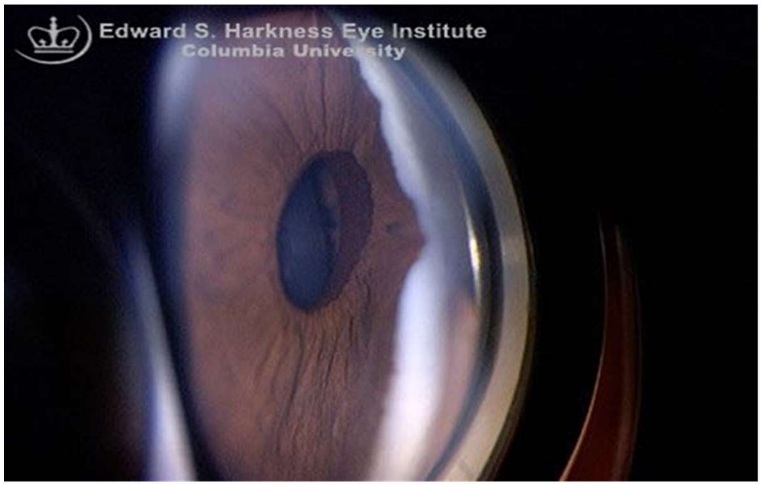
Figure 3: Recurrent bleeding [12]



Glaucoma followed by optic atrophy occurs in 10-20 % of patients with traumatic hyphema due to trabecular meshwork damage or due to peripheral anterior synechia which leads to secondary open angle glaucoma.

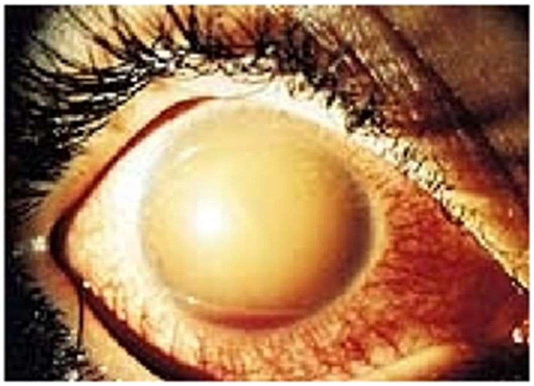
Another complication that can occur in an untreated hyphema is synechiae formation (Figure 4), both posterior synechia and peripheral anterior synechia. Peripheral anterior synechia are more common and occur after inflammation or persistent blood clot. Patients with hyphema dating more than 7 days have a higher risk of developing synechiae.[10]

Figure 4: Peripheral Anterior Synechiae [13]



Corneal blood staining (Figure 5) is the corneal impregnation with intra and extracellular hemoglobin and hemosiderin particles. This occurs in 2-11% of cases, particularly in cases of total hyphemas, increased intraocular pressure, recurrent bleeding, long persistent of a blood clot, corneal endothelial cell dysfunction. The first sign of corneal damage is the presence of fine, deep, yellow line in the stroma, especially central, followed by extension in 24 -36 hours. After the resolution of hyphema, cornea gradually clarify, in months or even years, from the periphery to the center.[15]

Figure 5: Corneal blood staining [14]



MANAGEMENT

The goals of the treatment are:

- clearing the hyphema
- reducing the bleeding rate
- treating the associated tissue lesions
- minimizing the long-term sequelae

Hyphema, unaccompanied by any complications, should be treated conservatively with a protective patch, limited activity, elevate the head of the bed at an angle of 30-45 degrees, so that the hyphema can settle out inferiorly and avoid obstruction of vision and limit the exposure of cornea to blood. The patient should be closely monitored during the first days when the risk of bleeding recurrence and increased intraocular pressure is higher.

Hospitalization is recommended in cases of noncompliant patients, patients with blood dyscrasias, with severe ocular and orbital damage, and patient with an increased intraocular pressure and sickle cell anemia.[16]

The medical treatment consists of administration of topical corticosteroids or, in severe cases, systemic corticosteroids to decrease inflammation associated with hyphema, topical cycloplegics (atropine 1% for 5 days: 1 drop/day in children, 1 drop x 3/ day in adults) to stabilize the blood-aqueous barrier, to decrease pain by relaxing the ciliary spasm and prevent the formation of posterior synechiae, topical aqueous suppressants (beta-blockers and alpha-agonists) or systemic carbonic anhydrase inhibitors and hyperosmotic agents (acetazolamide or mannitol – 1,5 mg/body weight) if topical management fails to control the pressure, antifibrinolytic agents (aminocaproic acid – 50-100 mg/body weight every 4 hours, up to a maximum of 30 g/day, for 5 days, tranexamic acid) to reduce the risk of recurrent bleeding.[4,15,17]

Surgical intervention is required in approximately 5% of cases with the following indications: IOP elevation > 50 mmHg for 5 days, IOP elevation > 35 mmHg for 7 days to avoid optic nerve damage, IOP elevation > 25 mmHg for 5 days in cases of total hyphema to prevent corneal blood staining, IOP elevation > 25 mmHg for more than 24 hours at patients with sickle cell anemia, large stagnant clots persisting for more than 10 days to prevent peripheral anterior synechia formation.[16]

Surgical techniques are paracentesis/ AC washout for liquid blood – is the safest and simplest method able to evacuate circulating red blood cells, can be repeated, avoid affecting the conjunctiva in case of a possible future filtration surgery, provide control of intraoperative bleeding and fast reduction of intraocular pressure, and bimanual cutting/aspiration for clotted hyphema, using the vitrectomy probe. Other surgical interventions that may become necessary include: peripheral iridectomy and trabeculectomy for glaucoma, cyclodiathermy and ultrasonic emulsification and aspiration.[10]

PROGNOSIS

Prognosis for visual recovery is related to the following factors: amount of associated damage to other ocular structures (choroidal rupture, retinal detachment, posttraumatic macular edema, lens opacification, vitreous hemorrhage, and angle-recession glaucoma), whether secondary hemorrhage or complications such as glaucoma, corneal blood staining or optic atrophy occur.

Studies have demonstrated that more than 75% of patients have a good prognosis, so approximately 80% of patient with hyphema <1/3 AC regain visual acuity of 20/40 (6/12) or better, 60% of patient with hyphema >1/2 AC but less than total of AC regain visual acuity of 20/40 (6/12) or better, while only 35% of those with total hyphema have good visual results. Poor visual outcome in traumatic hyphema can be directly attributed to the hyphema in 11% of patients; the poor visual outcome is usually the result of secondary hemorrhage associated with optic atrophy or corneal bloodstaining.[10,16]

Immunopathogenesis and treatment of ulcerative colitis: from modern medicine to herbal medicines

Farshad N. Asiabani[1,2], Hadi E.G. Ghaleh[2], Soheil Vazifedust[2], Ahmad R.S.O. Abadi[3]

Abstract: *Ulcerative colitis is one of the idiopathic inflammatory diseases of the large intestine with an unknown cause, which occurs in recurrent attacks of inflammation in the lining of the mucosa and below the intestinal mucosa. Impaired mucosal immune responses, the involvement of inflammatory cytokines such as IL-1, TNF-α, and IL-6, and other inflammatory mediators such as arachidonic acid metabolites play an important role in the immunopathogenesis of ulcerative colitis. Based on medical findings on the pathogenesis of the disease, new therapies have focused on the responses of the intestinal immune system and the inflammatory process. However, the widespread use of treatments such as aminosalicylates and corticosteroids continues. Most of these drugs have severe side effects. Some patients do not respond well to these treatments and sometimes have to undergo surgery and colectomy. Therefore, extensive studies are being conducted to control and prevent disease to use natural treatment methods such as the use of antioxidants with the approach of removing free radicals that prevent the destruction of cells and tissues in the body. Today, various studies have pointed to the effects of herbal medicines as a complementary treatment in inflammatory diseases. Their low cost and high effectiveness have attracted the attention of researchers in this field. The aim of the present study is a comprehensive review of modern and traditional treatments based on herbal medicines in the field of ulcerative colitis.*

Keywords: *inflammatory bowel disease, ulcerative colitis, immunopathogenesis, modern medicine, herbal medicine*

INTRODUCTION

Ulcerative colitis (UC) is a type of inflammatory bowel disease (IBD) characterized by uncontrolled inflammation of the large intestine and rectum. The prevalence of UC has increased in the last two decades [1]. Due to the unknown causes of the disease, the high risk of recurrence, and the poor prognosis, UC has become a clinical challenge in terms of treatment. One of the prominent features of this disease is excretion in the form of bloody diarrhea. The disease is characterized by periods of recovery and relapse that may occur spontaneously or in response to treatment [2]. However, conventional therapies for UC treatment, in addition to being successful and preventing recurrence, may lead to a variety of side effects [3]. UC is characterized by innate immune responses. Neutrophils, the first line of innate immune cells, are responsible for intestinal tissue damage by releasing large amounts of toxic components and free radicals during stimulation during UC progression [4, 5]. Meanwhile, the response of type 2 T (Th) helper cells, including over-activity of normal T cells and non-classical killer cells and Th2 cells, and significant production of cytokines, e.g. IL-5 and IL-3, have been reported in the pathogenesis of UC. Higher cytokine levels have been reported in patients with UC, including IL-5, IL-13, and other

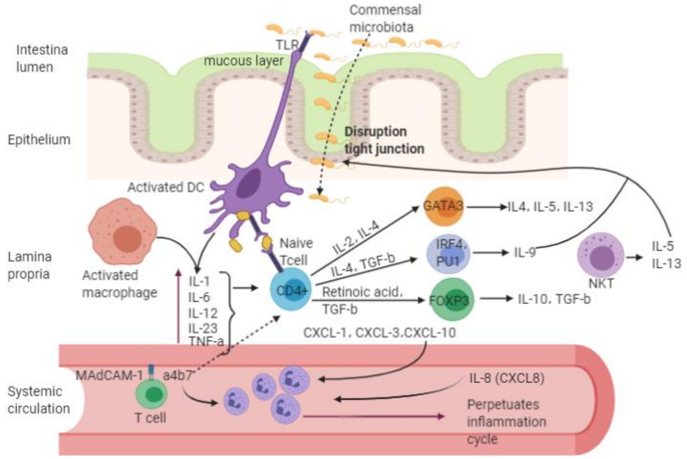
proinflammatory cytokines such as tumor necrosis factor (TNF) (Figure 1).

Figure 1: Cytokines involved in ulcerative colitis.



Created in BioRender.com

After the release of immune cells, cytokines act to stimulate immune responses further, induce epithelial cell apoptosis, and regulate expression (claudin-2), here as damage to the epithelial barrier leading to disruption of the epithelial barrier. They become tightly connected to the intestinal epithelial cells [6-8]. Nuclear factor-kappa B (NF-κB) is a transcription factor responsible for the expression of a variety of genres, for example, TNF-α, in response to extracellular inflammatory stimuli [9]. Because high levels of TNF have been reported in the blood [10], fecal samples [11], and mucosa [12] of patients with active UC, it is widely accepted that NF-κB plays a pivotal role in UC progression. The association of NF-κB inhibition in IBD has been further demonstrated by the experimental treatment of colitis with an anti-NF-κB oligonucleotide that improves inflammation in the colon [13]. Infiltration of neutrophils and macrophages into the mucosal tissue of the colon is an important feature of ulcerative colitis. Activated neutrophils in the intestinal mucosa produce and secrete reactive oxygen species, including superoxide ions, hydroxide radicals, and hydrogen peroxide [14]. These factors cause lipid peroxidation, increase the permeability of mucosa and blood vessels, increase the entry of neutrophils into the mucosal tissue, and the development of inflammation [15]. Reactive oxygen species damage the intestinal wall, cause ulceration, bleeding, and diarrhea by affecting cytokine genes and enzymes involved in the inflammatory response. Oxidative stress also reduces antioxidant factors as a result of increasing disease severity [16, 17]. On the other hand, patients with ulcerative colitis are at risk for colon cancer for two reasons: lack of inflammation control and drugs such as anti-tumor necrosis alpha. The risk of cancer in these patients begins to increase after 8-10 years and increases by half to one percent per year [18-21]. For this reason, research is ongoing to find effective treatment with few side effects. The use of antioxidants can be effective in controlling the disease and preventing its recurrence. Antioxidant compounds can prevent cell damage by neutralizing free radicals [22]. Herbal medicine has been used for centuries as one of the most traditional medicine methods and clinical treatment of many diseases such as infections and functional disorders. Recently, the potential effect of herbs has been suggested as a UC treatment. But drugs such as aminosalicylates, corticosteroids, and immunosuppressants continue to be widely used. Amino salicylates are administered orally or topically (suppository and enema) and are safe and effective drugs and are always one of the first treatment options in the treatment of patients with mild to moderate forms of the disease and also for persistence. They are used to relieve symptoms. Corticosteroids are one of the most common therapy inactive diseases. These drugs can be given topically, orally, or intravenously. They have a great effect on active disease control but are not suitable for reducing symptoms in the long run (or maintenance treatment). Immune-suppressing drugs or immunosuppressants are also used to treat colitis. These drugs reduce inflammation but do so by suppressing the immune system response (which initiates inflammation) [23]. However, there is a constant effort to find better drugs. The aim of this study is a comprehensive review of modern and traditional therapies based on medicinal plants in the field of ulcerative colitis.

DISCUSSIONS

Modern medicine in the treatment of ulcerative colitis

As mentioned, the etiology of inflammatory bowel disease is unknown. Still, the influence of genetic predisposition, environmental factors, and immune system on each other has been evaluated, and the use of corticosteroid anti-inflammatory drugs, aminosalicylates, antibiotics, immunomodulators, and biological materials. They are effective methods in the treatment of ulcerative colitis [24]. Most of these drugs have severe side effects, including diarrhea, vomiting, fever, rash, growth retardation, anemia, and osteopenia, increased risk of infection, liver disorders, kidney disorders, pancreatitis, and gastrointestinal ulcers. Also, besides not all patients respond ideally to these therapies, and sometimes there is no choice but surgery and colectomy [25]. Prevention of colectomy, prevention of disease complications and death; and controlling inflammation with the least side effects of drugs are some of the important goals in treating ulcerative colitis [26]. In this part of the article, we describe modern medicine in the control and treatment of ulcerative colitis.

Amino salicylates

Amino salicylates have always been one of the first drug choices in treating patients with mild to moderate disease activity.

Sulfasalazine

Sulfasalazine is a combination of an antibacterial agent (sulfapyridine) and a salicylate (5-aminosalicylic acid). It was originally designed to treat rheumatoid arthritis and was first introduced in 1942 as a drug to treat inflammatory bowel disease (IBD). The effective therapeutic agent in treating IBD is 5-aminosalicylic acid and sulfapyridine is the only inactive carrier that allows this effective substance to be released in the colon. Despite the relative absorption of this drug in the small intestine, approximately 90% of the drug reaches the large intestine. After absorption in the large intestine, 20% of 5-aminosalicylic acid undergoes hepatic acetylation and is excreted in the urine. Approximately 15% of patients treated with sulfasalazine experience significant side effects that necessitate discontinuation of the drug [27-29].

Pentasa

One of the most common products is mesalazine, which contains micro granules coated with ethyl cellulose. The release of mesalazine in this product starts from the duodenum it continues throughout the small intestine and colon so that 50% of the 5-aminosalicylic acid of this product is released in the small intestine [28, 30]. Pentasa is a type of mesalazine released at the end of the ileum and colon, in a pH-dependent manner. The release of 5-aminosalicylic acid in this product, which occurs in the small intestine (release at pH above 7), is about 15-30% [28-32].

Closal

Used to treat active disease, it contains the 5-aminosalicylic acid molecule, which is attached to a benzoic acid derivative by azo. In the colon environment, 5-aminosalicylic acid is released by the bacterial enzyme reaction. Like sulfasalazine, almost the entire drug is transported intact to the colon, and its metabolites are rapidly excreted in the urine [33, 34].

Corticosteroids

Corticosteroids are one of the most common therapy inactive diseases. Prednisolone at a daily dose of 40 to 60 mg effectively treats severe to moderate disease the use of such systemic steroids should be limited to severe and refractory cases. Studies have shown that long-term use of corticosteroids does not affect the treatment of this disease. Although no study has directly compared the therapeutic effect of oral corticosteroids with injectable therapy, the injectable form is commonly used in more severe cases. Importantly, corticosteroids are not effective in maintaining improvement in ulcerative colitis, in addition to the side effects associated with corticosteroid use [35, 36].

Budesonide

Initially used to treat asthma and allergic rhinitis, it is structurally different from prednisolone. This structural difference has resulted in more local anti-inflammatory activity and a higher affinity for receptors than prednisolone. Budesonide has a metabolism of about 90% in the first hepatic passage. This low systemic bioavailability reduces the toxicity of the drug. The effect of oral budesonide in treating endoscopic findings similar to prednisolone has been reported [37, 38].

Antibiotics

Bacterial flora plays an important role in the pathogenesis of inflammatory bowel disease. In the case of infectious complications of inflammatory bowel disease, antibiotics have a therapeutic role in cases where the disease is active. But unlike Crohn's disease, these drugs are not very effective in treating an active disease or maintaining recovery in patients with ulcerative colitis [39, 40].

Immune-regulating drugs

The use of these drugs in the clinic for patients with inflammatory bowel disease is mainly due to the following reasons: 1 - Chronic active disease; 2 - Steroid-dependent disease; 3 - Long-term maintenance of disease recovery after treatment with biological agents; 4 - Prevention of the immune response to biological agents. Patients treated episodically with infliximab show a greater immune response to these agents, and concomitant use of immunomodulatory drugs reduces the immune response to Infliximab [41, 42].

Methotrexate

It is a folic acid antagonist that has anti-metabolic and anti-inflammatory activity. It is used in patients with Crohn's disease. Intramuscular injection of MTX at a weekly dose of 25 mg for 16 weeks is effective in patients with active Crohn's disease. A controlled study reported that a low oral dose of MTX of 12.5 mg per week was not effective in treating active ulcerative colitis. However, no controlled studies have been performed on the role of subcutaneous or intramuscular MTX in the active disease of ulcerative colitis [43, 44].

Cyclosporine A

This drug has been considered due to its immunomodulatory properties and therapeutic effect in patients with inflammatory bowel disease. Cyclosporine A may be appropriate in severe, fulminant, as well as steroid-resistant cases. For example, continuous infusion of cyclosporine can be effective in patients with severe colitis who have not responded to steroid therapy after 7 to 10 days. In one study, 82% of patients with active disease who did not respond to steroid therapy responded to intravenous cyclosporine-4 therapy. After six months of follow-up, 44% of respondents eventually underwent colectomy despite continuing maintenance treatment with oral CYA (45, 40). It seems that immunomodulators' use is effective in avoiding colectomy after induction of recovery by cyclosporine [45].

Immunosuppressive

Immunosuppressive drugs are commonly used when treatment with aminosalicylates and steroids is not effective or when steroids cannot be stopped to reduce inflammation without reactivating the symptoms and relapse. If the patient is dependent on treatment with steroid drugs, this method can be considered to receive immunosuppressive drugs, and then, slowly reduce or even stop using steroids without recurrence of inflammation. Slowly, for this reason, immunosuppressive drugs are sometimes called "steroid-sparing" drugs. In this group, azathioprine (Imuran, 2 to 2.5 mg/kg per day) and its active metabolite (6-mercaptopurine 6-MP); (1 to 1.5 mg/kg per day) as well as methotrexate and cyclosporine. Azathioprine and 6-mercaptopurine are effective treatments for persistent remission in both Crohn's disease and ulcerative colitis. Although their onset is slow (months), they are generally uncomplicated and well-tolerated. Other treatment regimens include intramuscular methotrexate to induce remission (15-25 mg weekly) and persistence remission (15-25 mg per week) in active Crohn's disease, as well as intravenous cyclosporine (2-4 mg/kg daily). Title Facilitators for severe ulcerative colitis are steroid-resistant. Due to the possibility of short-term or long-term side effects, and the need for careful follow-up, patients who need these drugs should be treated by a gastroenterologist [46].

Biological therapies

Recent advances in medical knowledge regarding the pathogenesis of inflammatory bowel disease have led to the introduction of new therapies that target specific aspects of the immune system and inflammatory processes in inflammatory bowel disease. One of these included in clinical therapy is treatment with anti-TNF-α. This cytokine drug is a key factor in the pathogenesis of inflammatory bowel disease. To date, only Infliximab (Remicade®), Certolizumab (Cimzia®), and Adalimumab have been shown to have a significant effect on inflammatory bowel disease. Recent data have shown that Infliximab is effective in inducing and maintaining recovery and the gradual reduction of steroids in patients with ulcerative colitis It should be noted that due to the increased risk of infection in patients using these drugs, examination of infectious foci such as chest mammography test before starting treatment is necessary [47-49].

Traditional medicine with a focus on herbs in the treatment of ulcerative colitis

Different types of herbs are used to control inflammation or reduce the symptoms of colitis. The herbal medicine includes a wide range of therapies within and outside the realm of modern medicine. However, the effectiveness of medicinal plants has limited evidence. Potential benefits of medicinal plants include high acceptance of these drugs by patients, good efficacy, relative safety, ease of use, and relatively low cost.

The effect of herbs on hundreds of people has been tested in ulcerative colitis. However, it seems that all over the world, herbal medicine has been widely used to treat and control the disease. In this part of the article, we will discuss some studies on medicinal plants concerning the control and treatment of ulcerative colitis.

Aloe vera

Aloe vera is a tropical plant used in traditional medicine around the world. Aloe vera has anti-inflammatory activity and has been used by some doctors for patients with UC. Aloe vera gel is widely used orally by patients with inflammatory bowel disease and is undergoing therapeutic evaluations for this disease [50]. This study aimed to investigate the effects of aloe vera in vitro on the production of active oxygen metabolites, eicosanoids, and interleukin-8, all of which can be pathogenic in inflammatory bowel disease. The antioxidant activity of aloe vera in free cell systems, radical generator, and luminescence was evaluated in a colorectal mucosal biopsy sample. The production of eicosanoids was measured by sampling and measuring interleukin eight by Caco-2 epithelial cells in the presence of Aloe vera by enzyme-linked ELISA. The study's findings showed that aloe vera gel had a dose-dependent inhibitory effect on the production of reactive oxygen metabolites. Aloe vera inhibited the production of prostaglandin E2 but so far had no effect on the production of B2 thrombosis and also reduced the release of interleukin-8 by Caco-2 cells. The results of this study show the anti-inflammatory effects of aloe vera gel in vitro and confirm that aloe vera gel can have favorable therapeutic effects in the treatment of inflammatory bowel disease [51]. In another study aimed at investigating the effect of aqueous extract of aloe vera gel on gastric acid secretion and colonic histopathology in the model of induction of acute ulcerative colitis by acetic acid enema on 32 Wistar rats (200-250 g); The animals were randomly divided into four groups: healthy group, acetic acid-induced colitis group, aloe vera treatment group (for eight days) and sulfasalazine treatment group. After ether anesthesia, the animals were induced with acute colitis using acetic acid. After treatment, colon biopsies were removed from the distal 10 cm section for histopathological studies. The scoring system (Bita 2012) was used to compare histopathological features quantitatively. Stomach acid concentration was measured by the titration method. The results were considered as the mean and standard deviation of expression, and $P < 0.05$ was significant. The results showed that treatment with an aqueous extract of aloe vera did not reduce gastric acid. Histological results showed an inflammatory response in the ulcerative colitis group. Aloe vera extract reduced the severity of histopathological symptoms of ulcerative colitis, although it was less effective than sulfasalazine. Thus, it can be concluded that according to the improving effects of this extract, it seems that this plant can be used to eliminate colon disorders. However, further studies are needed to determine the effective dose of this plant in reducing gastric acid secretion [52].

Jujube

Jujube (Ziziphus Vulgaris Lam) has been known as a medicinal plant in East Asian countries since ancient times. It is used in traditional medicine in these areas to treat diseases such as liver disorders, anemia, shortness of breath, vomiting, and cardiovascular diseases. Hypertension and gastrointestinal disorders are used [53, 54]. Phytochemical studies on different jujube species have shown the presence of compounds such as cyclopeptide alkaloids, flavonoids, sterols, tannins, and Triterpenoid saponins, and the key role of these compounds in scavenging radicals and proven, free. Numerous effects, such as antioxidant and anti-inflammatory effects have been attributed to this plant [55]. In a study by Yue et al. (2015) on the protective effects of jujube on inflammatory bowel disease, they induced colitis by injecting TNBS (Trinitrobenzene sulfonic acid) into the rat colon and found that jujube polysaccharides They significantly reduced the severity of colitis, which was characterized by less weight loss, decreased score of disease activity index, and improved mucosal damage in rat colitis. Jujube polysaccharides also inhibit inflammatory responses and reduce tumor necrosis factor-alpha (TNF-α), interleukin-1 beta (IL-1β), interleukin-6 IL-6), and myeloperoxidase (MPO) activity in rat colitis. They also found that by examining tight junction proteins, jujube improves intestinal wall activity, thus protecting against inflammatory bowel disease by enhancing intestinal wall function [56]. In a study conducted by Karawya et al. (2016), regarding the effects of jujube on acetic acid-induced colitis, they concluded that increased levels of myeloperoxidase and caspase-3 are associated with changes in the crypts and destruction of goblet cells. By administering jujube extract, a significant decrease in myeloperoxidase and caspase three was observed compared to the control group. Jujube extract was also found to act as a treatment for acetic-acid-induced colitis in rats [57].

Turmeric

Turmeric is known by its scientific name (Curcuma longa). Curcumin is the active ingredient in the rhizome of the turmeric plant with the chemical name (diferuloylmethane). In addition to Curcumin, it contains several chemical compounds, including volatile oils, zinc, aqueous acids, and aqueous acids, oats, oats, and oranges in the yolk sac [58-60]. In traditional medicine, turmeric is known as anti-flatulence, and its consumption with food improves digestion and reduces bloating. Also, its effect on stimulating and producing bile and thus digesting fats improves digestion. Therefore, this substance in people with chronic gastrointestinal disorders and people who feel tired and bloated after eating is recommended. In laboratory studies, oral administration of aqueous and methanolic turmeric extract to rabbits significantly reduces gastric acid secretion and Ingredients of gastric juice, Oral administration of turmeric methanolic extract reduces gastric juice secretion. It prevents damage caused by histamine, indomethacin, rasping, mercaptamine, methanol, hydrochloric acid, sodium hydroxide, and sodium chloride on the stomach and duodenum [61-63]. In one study, administration of 300 mg of turmeric twice daily to patients with duodenal ulcers showed that after four weeks, about 50% of patients recovered. After 8 and 12 weeks, all patients achieved complete recovery without any side effects [64]. Also, in a study performed on 98 patients with ulcerative colitis, the effect of this herbal product at a dose of 2 grams per day in the treatment and prevention of recurrence of the disease was significantly better than placebo. In another clinical study performed on ten patients with gastric ulcers, administration of 1 gram of turmeric per day accelerated wound healing and reduced gastric pain [65].

Curcumin

In a study to determine the therapeutic effect of Curcumin on ulcerative colitis caused by sodium dextran sulfate (DSS) and discover the relevant mechanism, 60 mice were randomly divided into 6 groups. A was the normal control group, B was the model group, and group C was the 1.5 mg/kg dexamethasone group. Groups D, E, and F received 15, 30, and 60 mg/kg of Curcumin, respectively. Mice were killed seven days after treatment. The expression of TNF-α and MPO in colon tissue was determined by ELISA and the expression of P38MAPK mRNA and P.P38MAPK was evaluated by immunohistochemistry and RT-PCR. The results obtained in groups F, D, C, E, TNF-a, and MPO levels decreased significantly. P38MAPK mRNA expression was decreased in groups F, E, C, D, and there was a significant difference between E and F. As a result, Curcumin has therapeutic effects, which play an important role in the treatment of UC by inhibiting the P38MAPK pathway and thus reduce TNF-α. Because there is a risk of recurrence and cancer in UC patients and Curcumin has beneficial effects in preventing cancer, Curcumin can prevent cancer. It should also be noted that Curcumin is inexpensive and has no specific side effects, and can lead to a new generation of anticancer drugs [66].

Silymarin

Silybum is a flavonoid compound extracted from the sage plant. This plant is an annual or biennial of the chicory family distributed in Europe and some parts of the United States and Iran [67, 68]. The substance in the seed extract of this plant includes silybin A and B, silibinin, apigenin, dihydrosilibin, dioxycylcysteine, silycrestin, dioxylcydianine, etc. Dried seed extract contains 1 and 4% of silymarin, which contains flavonoids such as silybin A and B, silybinine, silycristine, and dihydroxycylin [69]. This plant has antioxidant and anti-inflammatory properties [70]. Silymarin also acts as a cell membrane stabilizer and cell glutathione enhancer, responsible for detoxification and free radical scavenging in the body. Laboratory data indicate that silymarin stimulates neutrophils and chemo toxic and phagocytic activity. It does not affect. But when neutrophils are stimulated, silymarin prevents the release of myeloperoxidase. Inoculation of neutrophils with silybin prevents the movement of leukocytes (FLMP) [71]. In a double-blind, placebo-controlled trial in patients with alcoholic cirrhosis, treatment with silymarin increased leptin secretion, which induced lymphoblast deformity. Also, the number of T8 cells was reduced, and lymphocytosis was significantly suppressed compared to the control group [72]. In a study to evaluate the effect of silymarin on acetic acid-induced colonic ulcers in mice, 32 adult, Blab/C mice, weighing approximately 36 4 4 g were divided into four groups of 8. The face was intact and without induction of disease, and the control group had an intestinal ulcer (colitis) and was not treated. The wound treatment groups were treated with 40 and 80 mg/kg silymarin. Rats in the treatment group received silymarin daily for 14 days before the onset of the disease and then for one week after the disease´s onset. The drugs were given orally. To make a wound, 1 ml of 4% acetic acid was injected intrarectally. One week after the wound was diagnosed, part of the colon was removed for histological studies, and colonic lesions were examined by the Morty method. Alkaline phosphatase concentration was measured by ELISA. The extent of tissue edema was also assessed. Based on the results, the concentration of alkaline phosphatase enzyme in the wound group showed a significant increase (P <0.05) compared to the control group. In contrast, in the silymarin groups, this increase was significant (0.05). P <0) was controlled compared to the colitis group. As a result, it can be said that the use of silymarin can be considered as a proposed method in the treatment of disease [73].

Chamomile

Chamomile, with the scientific name of Matricaria chamomilla, is an annual, fragrant plant with a height of 20 to 40 cm that goes by car on farms and roadsides. The plant is now widely distributed in Europe, West Asia, North Africa, North and South America, and Australia. Chamomile is one of the oldest medicinal plants known to man, and its use dates back to ancient Greece [74]. In to investigate the effect of aqueous this plant in the animal model of colitis induction by acetic acid, five groups of 7 adult male NMRI rats in the weight range of 280-230 g were tested. Three groups received different doses of aqueous extract of chamomile (30 mg/kg, 20, 10), and the fourth group received the solvent orally. The last group was considered the control group. To induce colitis, rats were kept on an empty stomach for 36 hours and then subjected to mild anesthesia with ether.

2 ml of 4% acetic acid was injected into the colon. Twenty-four hours later, macroscopic observations of the stool showed signs of colitis. The results showed that in this study an aqueous extract of chamomile at doses of 30 and 20 mg/kg significantly reduced the ratio of weight to colon length. Also, the highest dose of the extract (30 mg/kg) reduced the severity and extent of inflammation. Histopathological studies of the colon showed that the therapeutic effect of chamomile aqueous extract at doses of 30 mg/kg and 20, 10 is more complete with increasing dose. As a result, it can be concluded that aqueous chamomile extract is effective in the treatment of ulcerative colitis in this model and has significantly reduced inflammatory and ulcerative parameters of ulcerative colitis [75].

Ginger

Ginger, which is used as a spice in various parts of the world, is a complementary treatment for some diseases, especially gastrointestinal diseases such as nausea and vomiting, and its anti-inflammatory, antioxidant and anti-ulcer properties have already been proven. It is classified in the Emonographs Valley as a plant with its properties and drug interactions [76]. A study aimed at investigating the effect of ginger as an anti-inflammatory and antioxidant food on quality of life, disease activity and serum levels of some inflammatory factors and oxidative stress in patients with mild to moderately active ulcerative colitis 46 patients with colitis Mild to moderate active took four capsules daily containing 500mg of dried ginger root powder or similar placebo for six weeks with meals. Use of accurate and valid questionnaires and serum levels of total antioxidant capacity (TAC), malondialdehyde (MDA), Tumor necrosis factor α (TNF-α), high sensitivity C-reactive protein, and nuclear factor kappa B (NF-kB) were evaluated before and after the intervention. The results showed that ginger consumption reduced the level of serum MDA factor in the experimental group compared to the placebo group ($P = 0.04$). Also, Besides TNF-α and disease activity in the ginger group decreased after six weeks of intervention compared to the beginning of the study. There was an increase in urinary incontinence from 1% to 3% ($P > 0/05$). It was concluded that consumption of 2 g of dried ginger root powder for six weeks reduces oxidative stress in patients with mild to moderately active ulcerative colitis [77].

Turpentine (Pistacia atlantica)

One of the plants used in cancer treatment prescriptions is turpentine. It is known as Bane and grows in the cities of central and western Iran. The scientific name is turpentine (Pistacia atlantica) and from the family Pistachio or Anacardiaceous [78, 79]. This study aimed to evaluate the therapeutic and protective effects of turpentine oleoresin in acetic acid-induced colitis in rats. Turpentine oleoresin dissolved in twine 80 (1% v/v) at doses of 100, 200, and 400 mg Kg was administered orally to animals. In this treatment, three days after induction of colitis, mice were treated for six days. After determining the most effective dose in the treatment, in this method, the animals were treated for six days with the optimal dose of gum. Finally, for microscopic and macroscopic examinations, the animals were anesthetized with ether, and the colon was removed. Based on the results obtained in turpentine oleoresin treatment in a dose-dependent manner, it showed significant effects in inducing recovery in acetic acid-induced colitis in the rats ($P < 0.05$). But in the protective method, no significant difference was observed between the treatment and negative control groups ($P > 0.05$). The results of this study showed the beneficial anti-inflammatory and wound healing properties of turpentine oleoresin in the treatment of acetic acid-induced colitis in rats [80].

Frankincense (Boswell serrate)

Frankincense extract has been used for many years to treat arthritis, heal wounds and strengthen the female hormonal system. According to previous studies, frankincense can positively affect brain development and possibly the formation of dendrites and axons and improve the relationship between them [81]. Frankincense has been used as an anti-inflammatory, anti-arthritis؛ analgesic in treating diseases related to chronic intestinal diseases, asthma, cerebral edema, and other diseases. Several clinical studies have confirmed their biological activity, and studies that have specifically investigated the mechanism of action of this plant have confirmed their anti-inflammatory and anti-tumor activity. Bosolic-acids are considered the main active ingredient in frankincense and are responsible for its therapeutic effects. In a study aimed at investigating the therapeutic effects of frankincense, based on the results of studies reviewed in this article, frankincense with anti-inflammatory, anti-arthritis, antimicrobial, and analgesic effects and with the least side effects in traditional and modern medicine in the recommended therapeutic doses can be effective in treating many diseases [74]. In vitro, animal studies and models have shown that boswellic acid can inhibit selective 5-lipoxygenase with the effects of inflammation and arthritis [83]. Studies show that Bosolicacid derivatives have strong anti-inflammatory properties and do not have the known side effects of steroids. Among these derivatives, AKBA and KBA are the strongest inhibitors of the 5-LOX enzyme with IC IC502.8 and M1.5 In different clinical studies, the efficacy of frankincense extract at a dose of 300 mg 3 times a day has been comparable with sulfasalazine and mesalazine to treat Crohn's disease and colitis [84].In a study of 30 patients with chronic UC, 20 patients were given 900 mg of frankincense gum daily in 3 doses for six weeks, and ten patients were given 3 grams of sulfasalazine daily in 3 doses for six weeks. This study showed that frankincense has beneficial effects on the disease because 14 patients out of 20 patients were directed to recovery and 18 patients out of 20 patients showed improvement in one or more parameters. In the sulfasalazine group, 4 out of 10 patients showed improvement, and 6 out of 10 patients showed improvement in one or more parameters [85]. In animal models, studies have shown that frankincense is effective in the treatment of inflammatory bowel diseases, including colitis and Crohn's disease [86].

Licorice

Licorice (Glycyrrhiza glabra L) is a perennial herb [87]. Licorice root contains various compounds such as flavonoids, sterols, amino acids, starches, essential oils, and saponins. Its major saponin is glycerin or glycyrrhizin [88, 89]. In addition to the above compounds, licorice root contains other compounds such as beta-glucuronosyl-glucuronide, asparagine, goose, sucrose, resin, volatile oils, flavonoid compounds as well as Coumarin compounds [90, 91].

One of the most well-known therapeutic properties of licorice rhizome has been its use in gastric ulcers [92], and its flavonoids are anti-Helicobacter pylori [93]. Licorice derivatives increase the prostaglandins concentration, inhibit gastrin secretion, and increase the lifespan of gastric epithelial cells, thereby healing gastric ulcers [94]. Some studies indicate the effects of some compounds of licorice extract on the gastrointestinal tract.

Evidence has also reported that glycerin in licorice can improve intestinal mucosal inflammation in mice by reducing the expression of NF-κB, TNF-α, and ICAM-1 in inflamed mucosa [95]. Clinical studies on licorice combined with other herbs have shown that licorice can be effective in controlling UC [96]. The anti-estrogenic function of glycerin has been proven to be high in concentration. Glycerin binds to estrogen receptors, thus acting as an antagonist for estrogen. However, estrogenic activity has also been reported for licorice and attributed to its isoflavone compounds [97]. Studies show that glycyrrhizin may inhibit the effect of mineralocorticoids by acting on 11b-hydroxysteroid dehydrogenase. Evidence has shown that glycerin can also suppress plasma renin activity and aldosterone secretion. Also, besides studies have shown that licorice has chemoprotective effects through its effect on Bcl-2 /Bax and is also effective in inhibiting cancer [98, 99].

Ulmus fulva

Ulmus fulva is a plant that can naturally prevent inflammation and help heal damaged and injured gastrointestinal tissue. It also helps to facilitate excretion naturally. Ulmus fulva extract has a beneficial role in maintaining the health of the gastrointestinal tract, especially the stomach. It should also be noted that this plant plays an important role in eliminating nutritional deficiencies and electrolyte imbalances in the body. This effective herbal substance can help control possible anemia by stopping bleeding. This herbal substance is a supplement that is made from the bark of the Ulmus fulva tree and is in powder form. This plant has long been used by Native Americans to treat coughs, diarrhea, and other gastrointestinal ailments. A recent study on slippery elm as a supplement for the treatment of IBD confirmed the antioxidant effects of slippery elm for use in patients with IBD. Research so far has been promising, but the available evidence is insufficient for the widespread use of slippery elm in the treatment of IBD [100,101].

Triticum aestivum

Triticum aestivum is used to treat various gastrointestinal problems. In a study in which Triticum aestivum was used for one month in patients with UC with conventional colitis medications, clinical outcomes improved in 78% of patients. Those who received a placebo improved 30% of clinical outcomes. The dose of Triticum aestivum is initially increased to 20 ml per day and 20 ml per day to a maximum of 100 ml per day. Triticum autism appears to be effective and safe as an adjunct therapy in the treatment of UC [102].

Bromelain

One of these supplements has long been used as a wound healer in traditional medicine, one of which is pineapple [103]. Pineapple contains phytonutrients, vitamin C and Bromelain. Bromelain is derived from the root of the pineapple fruit, and according to laboratory and clinical studies, several properties have been mentioned for it [104, 105]. Human and animal studies demonstrate the beneficial effects of Bromelain in reducing pain, wound healing and burn debridement, as well as its anti-inflammatory, anti-edematous, anticoagulant and cumulative platelet inhibitory properties. The major pharmacological effects of Bromelain are related to its proteolytic properties [104-106]. Studies have shown that oral Bromelain decreases dose-dependently levels of bradykinin, plasmacins, prostaglandin E2, and thromboxane B2 in patients with inflammation [105, 107]. Bromelain, Bromelain selectively inhibits thromboxane and changes the ratio of thromboxane to prostacyclin in favor of anti-inflammatory prostacyclin [108]. Also, besides it has been shown that Bromelain stimulates leukocytes to increase interleukin-1, 6, 8 levels and alpha tumor necrosis factor in the inflammatory region. Increased cytokines, especially interleukin 8, lead to the uptake of granulocytes and monocytes into the inflammatory region and increase phagocytic and chemotactic, chemotaxis activity [104, 105, 109, 110]. The anti-edematous properties of Bromelain are due to increased vascular permeability following fibrinolysis and increased circulating edema fluid reabsorption. Fibrinolysis activity of bromelain has been attributed to increased conversion of plasminogen to plasmin. Plasmin also breaks down fibrin, thereby increasing vascular permeability [106]. Other studies have shown that nutritional supplements, including Bromelain, trypsin, and papain, are effective in wound healing [103]. Other experimental results also show that the combination of bromelain and trypsin is effective in wound healing and reduction of edema and inflammation in those who have undergone major abdominal laparotomy [111]. Bromelain has anti-inflammatory properties and is used as a facilitator of gastrointestinal excretion and blood thinner. It is also used to treat sports injuries, sinusitis, osteoarthritis, and swelling from bromelain. Bromelain has been studied for use as an adjunct in the treatment of IBD, especially treating ulcerative colitis. Emerging research on pineapple shows that bromelain is an active ingredient in pineapple that may help treat UC by relieving inflammation. The mechanism that is primarily responsible for its anti-inflammatory effects is still unknown. However, proteolytic activity has been identified for the anti-inflammatory effects of bromelain on T cell activation and cytokine secretion in vitro and mouse models of inflammatory diseases [112, 113]. The major anti-inflammatory mechanism of action of bromelain appears to be proteolytic activity. However, there is also evidence of hormonal activity, such as acting through the intracellular signaling pathway. Bromelain has been reported to help reduce cell surface receptors, such as the hyaluronic acid receptor CD4, which is involved in leukocyte migration and the induction of inflammatory mediators [114, 115]. Also, besides bromelain has been reported to significantly reduce CD4 T cells, which in animal models are the primary inflammatory factors in the gut [116]. In a study performed on a clinical trial of bromelain in the treatment of mild ulcerative colitis, clinical and endoscopic evidence showed improvement [117].

Qing Dai

Qing Dai herbal medicine is traditionally used in Chinese medicine to treat patients with UC, but there is a lack of published information about the effects of Qing Dai in the treatment of UC. In a study of the mechanisms of action of Qingdai, nine patients with active UC who received common medications but were willing to take Chinghai as an alternative drug were studied. UC severity was determined based on the clinical activity index (CAI). Also, besides 5 out of 9 patients were evaluated endoscopically based on the Mats grading system. Each patient received 2 grams daily of Qing Dai orally and continued with other UC medications as prescribed. Electron rotation resonance was used to discover the working mechanisms of Qingdao. After four months of treatment with Qingdai, the CAI score decreased. Similarly, the degree of endoscopic mats decreased. Six of the seven patients treated with prednisolone at the time of enrollment were able to discontinue the corticosteroids. Electron rotation resonance showed that Qingdai has a strong hydroxyl radical scavenging activity. Qingdai showed significant clinical and endoscopic efficacy in patients who failed to respond to conventional medications. Modification of the activity of hydroxyl radicals seems to be a potential mechanism by which this drug acts. Still, the final decision on the ability to produce therapeutic effects of Qingdai in the treatment of colitis is due to the anti-inflammatory effect of this drug in the treatment of UC patients has shown that further research is needed on the therapeutic effects of this herbal medicine [118].

Tea grass

Tea grass (Hypericum perforatum), a perennial plant with yellow flowers belonging to the Clusiaceae family, is used to treat anxiety, depression, ulcers, and as an antioxidant, analgesic, and nervous system protector [119]. This plant has antibacterial and antiviral effects [120], which acts by inhibiting the transcription factor NF-Kb [121] and with serine/threonine kinase) which belongs to the protein kinase C family (PKC) [122]. Tea grass has a significant effect on wound healing and an anti-inflammatory effect [123]. The beneficial effect of tea grass on the healing of oral mucosa in the golden hamster has been investigated [119]. In a study, the effects of tea grass on histopathological changes and Malondialdehyde (MDA) levels obtained from colonic tissue of rats with colitis were evaluated. Seventy male Sprague Dawley rats were divided into seven equal groups. Colitis was caused by acetic acid in them. Groups 1 and 2 received one cc of oral solution at 600 and 300 mg, respectively. In groups 3 and 4, 1 cc of the gel was enema 20% and 10%, respectively. In group 5, 1 cc of Asacol was injected as a positive control group, and one cc of normal saline was injected as a negative control group in group 6. Group 7 received only the base gel via enema. Rat colon samples were evaluated for histopathological changes and tissue MDA after seven days of treatment. Based on the results, tea grass extract in both oral and enema forms had reduced therapeutic effects on the rats' tissues in which colitis had developed by reducing MDA activity. In the enema form, 20% gel showed a better effect than 10% gel. In the oral form with a dose of 600 mg/kg, a better therapeutic effect was observed than 300 mg/kg. Therefore, it can be concluded that tea grass can be used as a treatment of choice, especially in the form of enema in colitis [124].

Other treatments under consideration

As medical knowledge of the pathogenesis of inflammatory bowel disease progresses, the search for more effective treatments with fewer side effects continues. Some of these new therapies for Crohn's disease include Certolizumab and Adalimumab.

The treatments under consideration for the treatment of ulcerative colitis include peroxisome proliferator-activated receptor gamma (PPAR-anti-visilizumab, gamma) integrin therapy [32].

CONCLUSIONS

At present, medical treatment for ulcerative colitis is not entirely desirable, and none of the drugs that are now available and commonly used to treat this disease completely cure the disease. Continuous advances in the basic sciences related to ulcerative colitis provide the basis for further understanding of the cause of this disorder. Studying herbal medicines and using them in combination with other medicines used in the treatment of ulcerative colitis can open bright horizons for doctors to control this disease, which of course for the use of herbal medicines along with modern medicine. Extensive studies are needed.

We hope that these studies will lead to more specific and effective treatments for the complete cure of these diseases.

Acknowledgments

The authors wish to thank all staff of Gastroenterology and Liver Disease Research Center Baqiyatallah University of Medical Sciences, Tehran, Iran, and Applied Virology Research Center, Baqiyatallah University of Medical Science, Tehran, Iran, for their cooperation in implementing experimental procedures and analysis of data.

CLINICAL PRACTICE

Improving the outcomes for pregnancies in the context of kidney disease

Mona Zvâncă[1,2], Aida Petca[1,2], Oana Baltă[2], Mihaela Boț[1,2], Claudia Mehedințu[1,3], Nicoleta Măru[1], Răzvan Petca[1,4]

Abstract: *Renal disease in pregnancy is a rare pathology, but it raises several problems in terms of normal pregnancy evolution. Among pregnant women with renal injury, the rate of complications such as spontaneous abortion, preeclampsia, hypertension, intrauterine growth restriction, premature birth, fetal and neonatal mortality are much higher.*

For a good understanding of the pathology and a correct management of pregnant women with renal disease, it is necessary to know the normal pregnancy changes and the differentiation of chronic kidney disease from the acute injuries occurring during pregnancy.

It is useful to ensure counseling prior to conception and to perform all prophylactic measures in order to prevent pregnancy complications and subsequent decline in renal function in all cases of pregnant women with chronic renal insufficiency.

Treatment of acute renal failure in pregnancy involves therapy of the underlying condition that caused renal injury, prevention of irreversible kidney injury and pre-vention of maternal and fetal secondary complications. Monitoring carefully this cate-gory of pregnant women, although additional risks strike, often results in favorabl pregnancy evolution.

Keywords: *pregnancy, chronic kidney disease, acute renal failure, complications, preeclampsia*

INTRODUCTION

Chronic kidney disease (CKD) affects 3% of pregnant women and represents an isolated risk factor for the occurrence of complications such as preeclampsia, arterial hypertension, premature birth and intrauterine growth restriction [1]. Such complications are not the only challenges that women with kidney disorders face during pregnancy, adding the potential teratogenicity of medications and the risk for disease progression. The management of chronic kidney disease in the context of pregnancy has lately become increasingly relevant to the practicing obstetrician, women becoming pregnant at more advanced age. Challenges brought by the presence of an underlying disease in pregnancy, such as autoimmune disease or diabetes mellitus, raise the necessity of interdisciplinary medical team to ensure satisfying maternal and fetal outcomes. The presence of acute kidney injury in pregnancy is generally declining worldwide, but still remains a significant health concern in developing countries, where pregnancy might be the first time to diagnose the kidney disease or the hypertension. Acute kidney injury affects a very small number of pregnant women and in this case the renal function decreases rapidly. The etiologies of acute kidney failure are diverse and require specific treatment [2-4]. It is critical to understand and evaluate normal physiologic changes in pregnancy in order to establish the proper diagnosis. The most common causes of chronic kidney disease are diabetes mellitus and hypertension [5]. Preconception counseling is required for women known with renal insufficiency, so patients would

understand the potential risks of pregnancy and make various changes of the treatment for kidney disease, so the therapeutic agents won't affect the pregnancy's normal course [2, 5]. There are cases in which, through serum and urinalysis investigations carried out at the beginning of the pregnancy, patients are diagnosed for the first time with chronic kidney disease [5, 6].

PHYSIOLOGICAL CHANGES OF THE RENAL FUNCTION DURING PREGNANCY

The pregnancy changes in the renal and urinary tract are both anatomical and functional [2, 7]. Anatomically, the renal volume increases up to 30 %, attributed to the expansion of kidney vascular and interstitial volume, by approximately 1-1.5 cm, predominantly at the level of the collector system. A certain degree of ureteral and renal pelvis dilation occurs, mainly secondary to progesterone-induced relaxation of the muscular layers and due to mechanical compression on the ureters themselves [2, 8]. In almost 86% of pregnant women is a right-sided preponderance of hydronephrosis, attributed to the right ureter peculiar anatomy, crossing over the iliac and ovarian vessels at an angle before entering the pelvis, while the left ureter passes at less acute angle and travels in parallel with the ovarian vein [9]. As a result, these changes should not be interpreted as hydronephrosis during an ultrasound [2, 10].

From a functional point of view, during pregnancy, blood volume increases by up to 50%, systemic vascular resistance decreases, cardiac rate increases by up to 30%, blood pressure decreases in the first two trimesters, with a compensatory increase in heart rate, and returns to the values before the pregnancy in the third trimester. [5, 11, 12]. These cardiovascular changes lead to increased renal blood flow by up to 50%, increased filtration rate up to 30%, and serum creatinine levels decrease up to 20%.

PREGNANCY AND CHRONIC KIDNEY DISEASE

Chronic kidney disease is a pathophysiological process that ultimately results in end-stage renal disease through a progressive loss of nephron number and function that persist 3 or more months [5]. It affects up to 6% of women of childbearing age and is estimated to be associated in 3% of pregnancies. Although the etiology does not significantly influence the evolution of pregnancy, we underline the most common causes: diabetic nephropathy, chronic focal glomerulonephritis, systemic lupus erythematosus, scleroderma and nodulous periarteritis, chronic pyelonephritis, reflux nephropathy, polycystic kidney disease, chronic nephrolithiasis, post-nephrectomy status and congenital unique kidney [13-17] Women with chronic kidney disease are frequently impaired to make the renal adaptations needed for a normal course of preg-nancy. These patients often show the inability to increase levels of renal hormones leading to reduced expansion of plasma volume, normochromic normocytic anaemia and vitamin D deficiency [16]. Advanced renal dysfunction with poorly controlled underlying primary renal disease, associating proteinuria, frequently causing hypertension, are all significant risks for adverse maternal, fetal and postpartum renal outcomes. These are the main reasons to plan the pregnancies, whenever is possible, thus achieving the best outcomes, allowing the opportunity to counsel the future parents in advance and to optimize these risks.

Chronic kidney disease in pregnancy is classified according to serum creatinine levels in three categories:
- Mild-serum creatinine level < 1.5 mg/dl
- Moderate – serum creatinine level 1.5-2.5 mg/dl
- Severe – Serum creatinine level > 2.5 mg/dl [18].

Another important marker of renal function in pregnancy is proteinuria/24 h, also being a diagnostic factor for preeclampsia [18].

The pregnancies in patients with mild or moderate renal disease, normotensive, generally evolve favorably, although these patients' prone higher risks for complications compared to pregnant women with normal renal function. Pregnant women with severe chronic kidney disease are more exposed to complications such as intrauterine growth restriction or premature birth, but these cases are extremely rare, the fertility rate at this stage of the disease being low [1]. Although of great importance, the kidney function is not the only predictive factor for the pregnancy outcome, changes in endothelial function and active systemic disease are more likely to be involved.

It is considered that the pregnancy accelerates more rapidly the renal dysfunction due to proteinuria and hypertension, but there are insufficient data in this matter [1], moreover, several small single centre studies suggested that the rate of progression of renal disease to end stage is unaffected by gestation, despite the known fact that many women experience a temporary decline in renal function during pregnancy, given the pathophysiological effects of hyperfiltration [19].

MATERNAL AND FETAL RISKS

Preeclampsia

The risk of developing preeclampsia for pregnant women with renal disease is significantly higher compared to the general population. In mild renal dysfunction, the risk is 20%, and in the severe one increases up to 60-80%, compared to the 5% risk in the general population [5]. The main fetal risks generated by preeclampsia are the restriction of intrauterine growth and premature birth [14]. A reduction of the risk for preeclampsia by 25% was demonstrated by daily administration during pregnancy of 150 mg of aspirin [5, 20].

Renal function

The decline in renal function rarely occurs in women with mild disease, but the risk for moderate illness is 25% in terms of definitive loss of 25% of renal function [5].

Hypertension

Once placental development is fully achieved, by 16 weeks' gestation, a 50% rise in plasma volume occurs, and in the vast majority of women blood pressure falls, due to the vasodilator response accompanied by an elevation of the cardiac output, arterial underfilling, subsequent ADH release and the stimulation of the renin-angiotensinogen system. Relaxin may also play a role in this chain of changes, because it has been linked to ADH secretion and water drinking, while levels are increased during pregnancy. In the third trimester, blood pressure starts to rise, reaching almost the pre-pregnancy values.

Among patients with renal disease, preexisting pregnancy hypertension is common, but during pregnancy it becomes much harder to control, on the one hand, due to the adaptive changes in pregnancy in the second and third trimester [5,10] and on the other hand, by the inability to use therapeutic agents of election, as inhibitors of the conversion enzyme and receptor blockers for angiotensin [5].

To reduce maternal and fetal complications it is necessary to maintain blood pressure below 140/90 mmHg, but an important decrease below 120/70 mmHg was correlated with increased risk of fetal demise [21]. Therapeutic agents that can be used in pregnancy are Methyldopa, Labetalol, Nifedipine, and Hydralazine (Table 1) [1, 5, 10, 22-24].

Table 1: Drugs used in pregnancy for women with kidney diseases, diabetes or kidney transplant

Drug	FDA	Indication	Fetal/neonatal effects	Use in pregnancy	Teratogenicity
ACE inhibitors/ARB	D	Hypertension	Cardiovascular, central nervous system defects in first trimester, FGR and neonatal anuria in second and third trimesters, fetal renal tubular dysplasia, oligohydramnios, perinatal acute renal failure, and other major congenital anomalies	Stop at conception	Yes
Beta-blockers	C	Hypertension	FGR in first trimester Atenolol may cause fetal bradycardia in the first trimester	Labetolol often used first line Atenolol can be used safely later in pregnancy	No
Ca channel antagonists – nifedipine, amlodipine	C	Hypertension	Nimodipine is prohibited	Used second line with methyldopa or labetolol	No
Hydralazine	C	Hypertension		Used for more severe hypertension Used in combination with methyldopa or beta-blockers	No
Methyl-Dopa	B	Hypertension		Often used first line	No
Biguanides – Metformin	C	Diabetes		Administered from first trimester	No
Second generation oral sulfonylurea hypoglycemic agent – Glyburide	B	Diabetes	Neonatal hypoglycemia higher when compared to insulin	Administered from first trimester Does not cross the placenta	No
Isophane (NHP) insulin	C	Diabetes	Can cause fetal macrosomia, and due to increased oxygen requirements is a risk factor for fetal death	First choice long-acting insulin The most natural agent for hyperglicemia	No
Rapid-acting insulin analogues – Aspart, Lispro	C	Diabetes		May be preferable to start pre-pregnancy	No
Longer acting insulin anlogues: Detemir,Glargine	C	Diabetes		Few studies, but encouraging results	No

Prednisolone/IV methylprednisolone	C	Kidney transplantation	Rare – except at large doses (cataract, adrenal insufficiency and infection) Increased frequency of premature rupture of membranes	maternal side effects: glucose intolerance, hypertesion, weight gain, hirsutism, acne, cushingoid features, impaired wound healing, osteoporosis, mood changes	Possible increase in oral clefts and mental retardation
Azathioprine – Imuran	D	Kidney transplantation		Maternal increased risk of infection and neoplasia.	Crosses the placenta as an inactive form. No congenital abnormalities have been observed.
Calineurin Inhibitors	C	Kidney transplantation	Transient immune alterations in the neonate (Cyclosporine) Hyperkalaemia and renal impairment (Tacrolimus)	Increasingly used - they have decreased rejection episodes and improved survival in transplant recipients.	No
Mycophenolate mofetil	D	Kidney transplantation	Increased risk of miscarriage and congenital abnormalities. Congenital malformations of the external and middle ear, cleft lip and cleft palate, and other major structural malformations involving the eye, hands and fingers, cardiac, bowel and skeletal systems.	Should be discontinued before pregnancy	Yes
Sirolimus (Rapamune)	C	Kidney transplantation	Small-for-gestational-age infants and delayed bone ossification	Immunosuppressant that could be used during pregnancy	Has not been implicated in specific fetal malformations. Further investigations are required

Proteinuria

The gold standard to diagnose proteinuria of pregnant women is the 24-hour urine collection and quantification of urine proteins level. Even so, errors in timing and urine retention in the dilated systems make urine collections incomplete, because of the large volumes contained at one time in the upper urinary tract.

The increase of the excretory level of urinary proteins is associated with important risk for intrauterine growth restriction and increased risk for renal dysfunction. [18, 20, 21].

In patients developing nephrotic syndrome during pregnancy (proteinuria > 3g/day, albuminuria > 30 mg/L and edema) there is a high risk for thromboembolic accidents and maternal death, even if blood pressure is maintained at satisfactory levels. In this category of patients, anticoagulant prophylaxis with low molecular weight heparins is recommended, up to 6 weeks postpartum. [5, 25].

Preconception Counseling

As general rule, the conception should not be discouraged as long as possible risks are understood and careful monitoring of the pregnancy is available. [1, 14, 20]. It is necessary to discontinue and substitute therapeutic agents with teratogenic potential (Table 1).

Patients with active vasculitis or lupus should be advised to wait for the episode to end prior to the conception. [5, 26].

RENAL TRANSPLANTATION AND PREGNANCY

Maternal status and fetal development in posttransplant renal patients is favorable, significantly better when compared to pregnant women with advanced renal disease requiring dialysis, especially if the following conditions are fulfilled [1, 8]:

- Renal function is stable
- Minimum one year after renal transplantation; latest recommendations ex-tend the waiting period at 2 years, thus reducing the risk for allograft failure
- Proteinuria maintained under 1g/day
- Controlled hypertension
- Minimal doses of immunosuppressants required (prednisone, tacrolimus, azathioprine, ciclosporin) (Table 1)

- No prior or pending rejection of renal transplantation [5].

Thus, women with diagnosed advanced kidney disease are often encouraged to wait until after successful kidney transplantation to obtain a pregnancy. The reason for this recommendation is that fertility is improved after transplantation and the risks for pregnancy complications, such as preterm birth and hypertension, are much lower. Pregnancy is considered a sensitizing event, which can result in the formation of anti-HLA antibodies that may impend finding a future suitable donor.

The incidence of premature childbirth, intrauterine growth restriction and preeclampsia is higher compared to the general population and 30% of pregnancies will be affected by these complications.

Vaginal childbirth is not contraindicated in case of mothers with renal transplantation. When Caesarian section is preferred, the approach of the lower segment may be difficult due to the trajectory of the transplanted ureter. [1, 5].

DIABETIC NEPHROPATHY AND PREGNANCY

Lately, as women do tend to procreate later in life, diabetic nephropathy is probably becoming the most common CKD seen in pregnancy. Pregnancy in women with diabetes type 1 or type 2 is associated with a two- to four-time increased risk of pre-term delivery, preeclampsia and perinatal mortality compared with the general population [27]. Pregnancies in women with CKD associate poor placentation and fetal growth restriction, with an incidence of small for gestational age newborns of 31% [19]. It is rather unclear if growth restriction is based on poor placentation or on fetal hyperinsulinamia, but women with more severe renal impairment are exposed to a greater risk for pregnancies with poorly grown infants, despite maternal hyperglycaemia, thus antenatal documentation of fetal growth restriction has been linked with worse fetal outcomes than macrosomia.

The first clinical sign of kidney malfunction is microalbuminuria, and urinary albumin excretion of 30–300 mg/24 h, corresponding to a spot urine albumin/creatinine ratio of 30–300 μg/mg. The progression towards diabetic nephropathy is seen in all cases left untreated, when microalbuminuria becomes persistent proteinuria, associating hypertension and an unavoidably decline in GFR [28].

Diabetic nephropathy adversely affects the course of pregnancy by the following three mechanisms: development of severe hypertension superimposed on the deterioration of kidney function in the mother, preterm delivery due to high maternal blood pressure and preeclampsia, and fetal intrauterine growth restriction and fetal distress caused by placental insufficiency.

The prepregnancy preparations in women with diabetic nephropathy or microalbuminuria would comprise intensive glycaemic control, low-dose aspirin, and intensive antihypertensive treatment. The treatment with ACE inhibitors followed by strict metabolic control for at least 6 months, usually results in low levels of albumin excretion and it has been found to be associated with a high rate of successful pregnancy outcome [27]. On the onset of pregnancy, early in the first trimester, ACE inhibitors are linked to increased risk of congenital malformations [29], as for the last part of the pregnancy, are associated with abnormal fetal renal development and neonatal renal failure [30] therefore treatment with ACE inhibitors or AngII antagonists should be stopped before conception. In the event of an unplanned pregnancy, women with diabetic nephropathy which necessitates continuous treatment with blockers of the RAS (renin angiotensin system), can benefit from a shift to other antihypertensive drugs successfully in early pregnancy. Severe congenital malformations have been linked to poor glycemic control before pregnancy, therefore the goal is strict glycemic control and HbA1c as close to normal as possible, at least <7% is recommended [31, 32].

In all women with high risk for pre-eclampsia, treatment with low-dose aspirin is proven to have some preventive effect, thus, at least theoretically, the same treatment could be of benefit in women with diabetic nephropathy [20] and is recommended in American and British guidelines.

The goal for CKD and diabetic pregnacy should be BP <135/85 mmHg and urinary albumin excretion <300 mg/24 h, obtained with antihypertensive treatment with pregnancy-friendly drugs, strict glycemic control (HbA1c <6.0%) and low-dose aspirin.

For many years, a pregnancy in women with diabetic nephropathy was related to a decline in maternal kidney function and important perinatal mortality, but recent improvements in pregnancy management substantially reduced those risks.

Cesarean delivery should be considered for every case where fetal weight is estimated for more than 4500 g. Vaginal birth at 39 weeks gestation is safe whenever blood glucose levels are well controlled and kidney function is normal. In those cases with vascular complications and poorly controlled blood glucose, delivery should be considered at 36 0/7 to 38 6/7 weeks or even earlier, depending on maternal and fetal status [33].

ACUTE RENAL INSUFFICIENCY IN PREGNANCY

Acute renal insufficiency is defined as the sudden degradation of renal function, ranging from the slight decline in renal function to the necessity of renal function replacement therapy [3, 34].

In the first part of the pregnancy, infectious pathology and hypovolemia are the most common causes of renal injury, and in the second part of the pregnancy, the most frequent etiological factors are preeclampsia, placental abruption or severe anemia.

The best management of this pathology is possible using the classification of the acute renal insufficiency by the cause, as pre-renal, renal and post-renal. Pre-renal injury occurs predominantly secondary to hypovolemia, hemorrhage, congestive heart failure, sepsis. Renal insufficiency has as main etiologies acute tubular necrosis, renal cortical necrosis, thrombotic microangiopathy, preeclampsia, acute interstitial nephritis, and glomerulonephritis. Post-renal insufficiency occurs due to ureteropelvic block, but rarely causes bilateral renal injury [3, 5].

Clinically, pregnant women with acute renal insufficiency present oliguria, de-fined as a urine production < 0.5 ml/kg/h. [3, 35]. Another marker of renal injury is the increased level of serum creatinine, which is difficult to be appreciated due to its low level in normal pregnancy. Secondary to renal injury, as a compensatory mechanism for renal hypo-filtration, an increase in systemic blood pressure and intravascular volume appears and changes of urinary electrolytic values due to the action of the system renin-angiotensin-aldosterone [36-38].

Treatment of acute kidney failure involves treating the underlying condition that caused renal injury and focuses on the restoration of urine production, avoiding secondary injury and increasing renal infusion. The effects of this pathology on the fetus are diverse, specific to each etiology, and may require delivery, as in the case of preeclamsia or placental abruption. [39, 40].

CONCLUSIONS

Although the risk of complications in pregnancy in patients with chronic kidney disease is higher than in the general population, in most cases, with the correct management of pregnancy and kidney disease, the pregnancy has a favorable evolution. There are insufficient data to certify the pregnancy as a potential factor in the decline of the renal function.

Intensive pre-pregnancy antihypertensive treatment in patients with diabetic nephropathy and good glycaemic control results in preservation of kidney function and favorable maternal and fetal outcomes.

Acute renal insufficiency, occurring during pregnancy, may benefit from specific etiological treatment, but may also require emergency delivery.

Close obstetric surveillance and screening for kidney function is important to improve pregnancy outcomes in these high-risk pregnancies.

Inadequate perioperative control of modifiable risk factors in total knee arthroplasty and implications on functional results

Bogdan Cretu[1,2], Catalin Cirstoiu[1,2], Bogdan Serban[1,2], Sergiu Iordache[1,2], Adrian Cursaru[1,2], Mihai Costache[1,2], Stefan Cristea[1,3]

Abstract: *Diabetes and increased body mass index are two of the most associated comorbidities in patients undergoing total knee arthroplasty. With the number of patients undergoing knee arthroplasty increasing and with the incidence of diabetes and increased BMI, we can expect that in the coming decades the association of the two comorbidities will be frequent. An ethical issue arises when the patients who are refused for total knee arthroplasty are instructed to change the risk factors, and they fail either because of a mental problem or because of a physical problem.*

This study analyzes the effects of controlled, uncontrolled, uncomplicated and complicated diabetes on the rates of post-knee arthroplasty complications. The study proposes to evaluate obese patients in terms of functional outcomes and postoperative complications after total knee arthroplasty.

Keywords: *total knee arthroplasty, diabetes, body mass index, total knee arthroplasty complications, periprosthetic joint infection*

INTRODUCTION

Diabetes affects 8.5% of the Europe's population, and its prevalence increases with age [1]. It is one of the common comorbidities associated with patients over 65 years old undergoing total knee arthroplasty. The literature data suggest that one of 10 patients that are admitted for a total knee arthroplasty has associated diabetes, but the prevalence of diabetes is constantly increasing [2, 3]. This has important implications in the perioperative management of the total knee arthroplasty, with an increase in the number of patients with associated diabetes [4].

The risks of the association between total knee arthroplasty and diabetes are periprosthetic infections, deep vein thrombosis and stroke [5-9]. The risks are even higher for stroke and death when the diabetes is uncontrolled [10]. The risk of complications increases directly proportional to the value of glycated hemoglobin (HbA1c) [11]. This information allows the surgeon to change the risk even from the preoperative period.

Approximately 48% to 56% of patients with diabetes are developing osteoarthritis, which leads to decreased functionality, decreased physical activity and high mortality rates [12]. The current standard of treatment for knee osteoarthritis is total knee arthroplasty [13, 14, 15].

Given the increasing prevalence of both diabetes and osteoarthritis of the knee as they age, these patients are forced to coexist with these associated pathologies, but also with developed complications, which may result in the postoperative period [16, 17].

Obesity is one of the most important modifiable risk factors and at the same time is one of the most discussed in terms of increasing postoperative complications in total knee arthroplasty. Regarding the postoperative complications, there are data available that indicate the fact that an increased body mass index (BMI) will increase the risk of total knee arthroplasty, but there is no cut-off value to help

us make the decision to perform surgery on a patient or not [18-21]. Literature data indicate that patients with high BMI benefit from a functional outcome and an improved quality of life more than normal-weight patients [22].

An ethical issue arises when the patients who are refused for total knee arthroplasty are instructed to change the risk factors, and they fail either because of a mental problem or because of a physical problem.

This study analyzes the effects of controlled, uncontrolled, uncomplicated and complicated diabetes on the rates of post-knee arthroplasty complications. The study proposes to evaluate obese patients in terms of functional outcomes and postoperative complications after total knee arthroplasty.

MATERIALS AND METHODS

The study ran over a period of three years from January 2017 until Decembre 2019 and included a number of 446 patients. The following patient data were collected: age, sex, body mass index, preoperative blood glucose, preoperative HbA1c, diabetes status (controlled/uncontrolled, complicated/uncomplicated), WOMAC score (preoperative, 3 months postoperatively and 12 months postoperatively), history of periprosthetic infection or complications of the wound.

In the statistical processing, the data were classified into quantitative, such as WOMAC score, and qualitative, respectively, sex, age range, controlled or uncontrolled diabetes. The qualitative or nominal data were represented as graphs. The graphs were of the column type (Column) and point cloud (Scatter Plot). In addition, Box Plots were used to represent the WOMAC score at different periods of time, preoperatively, at 3 months and 12 months depending on the patient's BMI.

The inclusion criteria in the study were patients with total knee arthroplasty, patients with and without diabetes and those with known BMI. In addition, the exclusion criterion from the study was the loss of the patient's records.

RESULTS

The study included a number of 446 patients, 20 of whom had periprosthetic infections.

The distribution of patients BMI shows that 173 were normal weight, 234 overweight and 39 obese. The analysis of the data shows that the mean WOMAC score was:

- at onset according to the patients' BMI was not variable. Specifically, the normal weight patients had a mean WOMAC score of 51, overweight patients had an average WOMAC score of 51, and obese patients had an average WOMAC score of 47.
- at 3 months according to the patients' BMI was for normal weight 74, overweight patients had an average WOMAC score of 69, and obese patients had an average WOMAC score of 60.
- at 12 months according to the patients' BMI was for the normal weight 88, the overweight patients had an average WOMAC score of 80, and the obese patients had an average WOMAC score of 69.

The distribution of patients with periprosthetic infection according to BMI shows that 1 normoponderal patient, 7 overweight patients and 12 obese patients presented with periprosthetic infection.

The distribution of patients with controlled and uncomplicated diabetes according to periprosthetic infections shows:

- The category of overweight patients with controlled and uncomplicated diabetes also had periprosthetic infections. The evolution of the WOMAC score for patients with controlled and uncomplicated diabetes and who presented periprosthetic infections is 38.5 preoperatively, 43 at 3 months and 53 at 12 months.
- The category of obese patients with controlled and uncomplicated diabetes also had periprosthetic infections. The evolution of the WOMAC score for patients with controlled and uncomplicated diabetes and who presented periprosthetic infections is 45 preoperatively, 50 at 3 months and 55 at 12 months.

The distribution of patients with controlled and complicated diabetes according to periprosthetic infections presents:

- The category of overweight patients with controlled and complicated diabetes did not show periprosthetic infections. The evolution of the WOMAC score for the patients with controlled and complicated diabetes and who did not have periprosthetic infections is 45 preoperatively, 66 at 3 months and 75 at 12 months.
- The category of obese patients with controlled and complicated diabetes also had periprosthetic infections.
- The evolution of the WOMAC score for the patients with controlled and complicated diabetes and who presented periprosthetic infections is 41 preoperatively, 45 at 3 months and 50 at 12 months.

The distribution of patients with uncontrolled diabetes according to periprosthetic infections shows:

- The category of overweight patients with uncontrolled diabetes also had periprosthetic infections. The evolution of the WOMAC score for the patients with uncontrolled diabetes and who presented periprosthetic infections is 38 preoperatively, 46.5 at 3 months and 50 at 12 months.

- The category of obese patients with uncontrolled diabetes also had periprosthetic infections. The evolution of the WOMAC score for the patients with uncontrolled diabetes and who presented periprosthetic infections is 42 preoperatively, 48.5 at 3 months and 57.5 at 12 months.

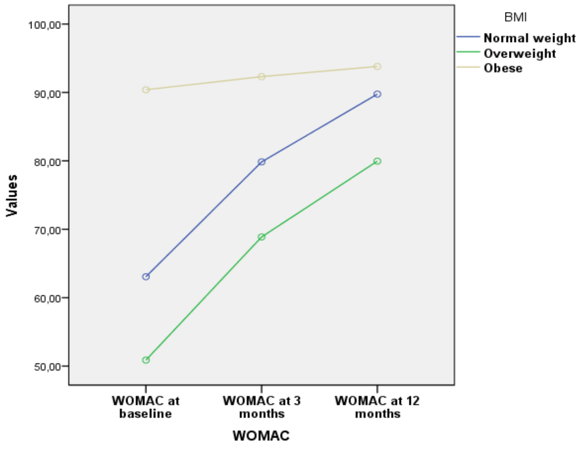
The ANOVA test with repeated measurements was used to investigate the evolution of the WOMAC score according to BMI. The Mauchly test showed that there are statistically significant differences both in BMI, WOMAC and in the evolution of BMIx WOMAC. Thus, for BMI, the Mauchly test had the value 0.97, p = 0.03, for WOMAC, it had the value 0.21, p = 0.001 and for WOMAC x BMI it had the value 0.04, p = 0.001.

The differences in BMI were as follows:
- Normal weight Vs. overweight (p = 0.001, 77.55 vs. 66.57);
- Overweight vs. obese (p = 0.001, 66.57 vs. 92.17);
- Normal weight Vs. obese (p = 0.001, 77.55 vs. 92.17)

The differences at the WOMAC level were as follows:
- WOMAC at baseline vs. WOMAC 3 months (p = 0.001, 68.11 vs. 80.34);
- WOMAC 3 months vs. WOMAC 12 months (p = 0.001, 80.34 vs. 87.84);
- WOMAC at baseline vs. WOMAC at 12 months (p = 0.001, 68.11 vs. 87.84).

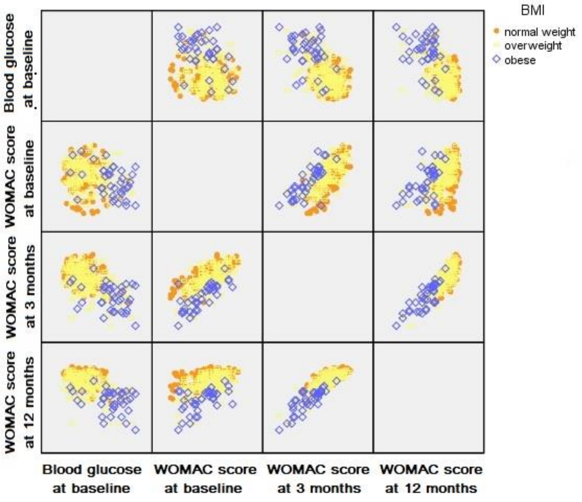
The average ANOVA score varies significantly depending on the BMI, respectively the WOMAC score at 12 months reaches the highest point for all types of BMI (Figure 1).

Figure 1: The evolution of the WOMAC score according to patient's BMI



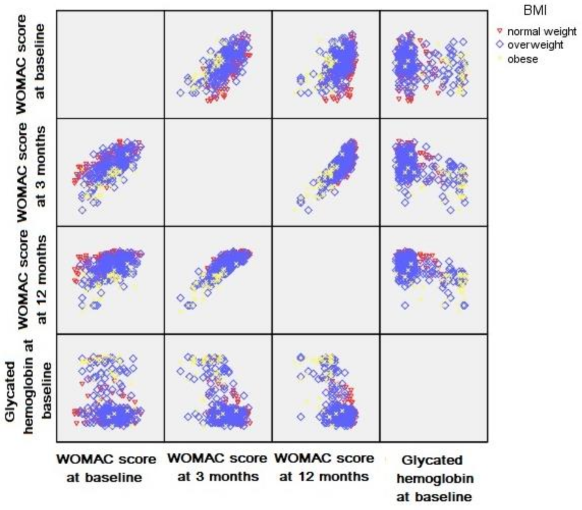
The distribution of patients' blood glucose according to BMI and WOMAC score reveals that the increased blood glucose levels at the WOMAC score time points were of obese patients (Figure 2).

Figure 2: The evolution of the WOMAC score according to patient's BMI



The distribution of glycated hemoglobin of patients according to BMI and WOMAC score reveals that the increased level of glycated hemoglobin at the time points of the WOMAC score were of overweight and obese patients (Figure 3).

Figure 3: The distribution of glycated hemoglobin of patients according to BMI and WOMAC score



DISCUSSIONS

Perioperative risks assessment is a standard in arthroplasty procedures. Careful exposure of the risks to the patient is essential for physician-patient communication. Total knee arthroplasty is not a risk-free intervention, as risks can range from the smallest (e.g. a small wound dehiscence) to complications with major functional impact such as periprosthetic infections.

Given that the incidence of gonarthrosis increases from year to year and the incidence of diabetes reaches alarming levels, the association of the two is inevitable. Diabetes is associated with a number of important complications for the patient. When a diabetic patient is proposed for arthroplasty, the risks are much higher than in a non-diabetic, which must be fully understood by the patient. In this discussion, an increased BMI, another associated risk factor, often occurs.

Most often, these patients are advised by current orthopedic doctors to follow a hygiene and diet regimen for weight loss along with trying to control diabetes and then move on to a knee arthroplasty. When providing such indications, it should be borne in mind that increased BMI along with uncontrolled diabetes are the result of many years of negligence and any attempts to change the weight or level of glycated hemoglobin will fail in most cases. The patient will return for arthroplasty with a level of glycated hemoglobin above normal, with BMI unchanged from the last visit, but with gonarthrosis that advanced due to the passage of time, which will lead to a possible arthroplasty with a risk of complications higher than initially.

It is ideal for these modifiable risk factors to be kept under control through multiple and careful consultations by patients with their specialists in diabetes. However, it should not be overlooked that sometimes this is impossible to achieve at an optimal level. An elderly patient, with a high BMI and uncontrolled diabetes, in the best-case scenario, after an average period, they will manage a moderate control of diabetes and the absence of its complications.

Adapting surgical techniques and perioperative care along with the assumption of potential risks, both by the attending physician and by the patient in such cases, is the optimal conduct.

CONCLUSIONS

Early diagnosis and correct treatment of diabetes are essential for optimal postoperative results after total knee arthroplasty. Immediate postoperative functional outcomes are also influenced by glycemic control. Optimal methods of preoperative glycemic control are needed to maintain a high level of functional outcomes as well as to limit the complication rates.

The functional results analyzed using the WOMAC score showed low values at 3 months postoperatively for overweight and obese patients compared to normal weight, but at 12 months they showed a significant improvement in functionality. The increases scores remain important compared to the preoperative level for these patients.

Periprosthetic infections occurred mainly in overweight and obese patients, obviously associated with elevated glycemic levels and elevated glycated hemoglobin.

The WOMAC score was low in all categories of patients with periprosthetic infection regardless of diabetes status. Overweight and obese patients with periprosthetic infection had a significantly higher level of glycated hemoglobin.

It can be said that the incidence of periprosthetic infections was predominantly higher in overweight and obese patients who associated diabetes regardless of status, but the functional improvements of these patients are remarkable compared to the preoperative level.

These perioperative and modifiable risk factors are becoming more common. The obese patient, with diabetes in various forms and with gonarthrosis is a current reality of the times and cannot be ignored. The decision to operate on such a patient should not be made by highlighting the potential complications that may occur postoperatively, the potential for a possible arthroplasty to improve the patient's quality of life and functionality are in the forefront and should dictate the operability decision.

Improving surgical techniques and the use of specific perioperative care techniques specific to an obese and diabetic patient should be considered to minimize the risk of a possible periprosthetic infection.

The diabetic, overweight, or obese patient with gonarthrosis will represent in the future an important share of all gonarthrosis patients. Thus, adapting the surgical approach of these patients to reduce the rates of periprosthetic infection represent one of the main solutions that can be applied.

The attempts to modify the lifestyle and eating behavior of an overweight or obese and diabetic person often fail for their diabetologists, which will lead to an advance of gonarthrosis, resulting in an arthroplasty grafted with a much greater potential for complications.

Indian experience of tetanus – A study from south India

V.S. Srikanth[1], Naidu Shravanthi[2], Ansar Ahmed[3], Tippeswammy[3], V.R. Mujeeb[4]

Abstract: *Introduction: Tetanus is an old world disease where 2 centuries ago people had realized the link between wound leading to muscle spasm and fatality, Even today there are many cases of fatalities of tetanus being reported from different parts of the country even after viability of a tetanus toxoid and Immunoglobulin injections. This one of very few recent studies done in India on tetanus, as there is very little data available on tetanus so we are trying to share our experience on tetanus, so it will help the physicians to get a better understanding.*

Materials and Methods: This retrospective study has done collecting the patients' detail from 2017- 2019, detailed case sheet review was done and the patients' clinical presentation and the prognosis were noted in predesigned format. Inclusion criteria – all diagnosed cases of tetanus, exclusion criteria – patient already received treatment from the local hospital. The patient details were kept confidential during all times.

Results: The total of 58 cases – 35 males and 23 females, The average duration of hospital stay was 15 days. The most common occupation were farmers (barefoot workers). The site of injury was the foot in 65% cases followed by injuries to the fingers or the hand in 30% and 5% cases due to injury while tooth picking with a pin, splinter removal using pins. Clinical symptoms – trismus "lockjaw" (41), difficulty in walking (2), limb pain/stiffness (17), back muscle pain/stiffness (12), dysphagia (7), 72% autonomic dysfunction. Opisthotonus position and risus sardonicus developed after 7-8 days of infection. 20% of cases were vaccinated still developed diseases. 18% mortality was noted most cases were unvaccinated cases.

Conclusion: Tetanus is preventable diseases if TT vaccination and IMMUNOGLOBIN are administered on time. In all primary health care levels, the cold chain should be maintained for vaccines. The patients should be made sensitized about the consequence of the disease process.

Keywords: *tetanus, bacterial infection*

INTRODUCTION

Tetanus is an old world disease, where 2 centuries ago people had realized the link between wound leading to muscle spasm and fatality. It was a disease that the ancient physicians of Egypt and Greece dealt with often, however, now its prevalence in developed countries has decreased significantly due to improvements in wound care and hygienic practices [1]. Arthur Nicolire isolated tetanus toxin from the soil in 1884 [2]. Even today it's a major health problem in developing countries and developed countries

(Anuradha 2006; Ogunrin 2009) [2, 3].

In 1884 the etiology was further understood. The first transmissibility was demonstrated by Antonio Carle and Giorgio Rattone who were pathologists in Turin They produced tetanus in rabbits by injecting pus from a person with fatal tetanus into their sciatic nerves [4].

Tetanus is a non-communicable, potentially fatal disease contracted by exposure to the spores of Clostridium tetani. It is a gram-positive, anaerobic spore-forming bacteria that produces an exotoxin called tetanospasmin which is responsible for the lethal effects of the disease. It is more commonly seen in developing countries as a result of low vaccination coverage, poorer medical care, and more risk of exposure [5].

Tetanus spores are present in the environment irrespective of specific geographical locations. Once the disease is contracted, it is difficult to manage despite even intensive advanced medical care if timely medical intervention is absent. The high infection and fatality rates in India could be a result of incomplete vaccination coverage, lack of awareness of the protocols to be followed after sustaining a wound, lack of resources in hard reach areas, lack of medical facilities in such areas [6].

Spores are present everywhere in the environment, more commonly in the soil of warm and humid areas. The dormant spores develop into active toxin-producing bacteria in the presence of a favorable environment, ie devitalized, dead or necrotic tissue. They enter the human system via open or infected wounds, or even through unclean delivery practices, burns, dental procedures, or surgeries. The toxin, tetanospasmin thus produced by the active bacteria results in widespread sustained contraction and spasm of the muscles in the body, i.e dystonia. This is via the prevention of the release of the inhibitory neurotransmitter Gamma-aminobutyric acid (GABA) into the synaptic cleft. This results in manifestations such as pain, headache, trismus, stridor, laryngeal spasm, rigidity, opisthotonus, and stiffness [7].

Dystonia can manifest in various ways, such as with tortipelvic, torticollis oculogyric, buccolingual, or opisthotonic [8].

The prognosis of a case can be assessed via the Phillips scoring system (Table 1).

The spasms are most in the first 2 weeks, the autonomic disturbances following them by a few days and peaking in the second week. The muscle spasms and convulsions are often precipitated by even minor stimuli, such as light, touch, or noise. The severe spasms and muscle rigidity often necessitate paralysis in cases of tetanus. Autonomic disturbances occur in the form of labile hypertension, sweating, tachycardia in severe cases.

Table 1: Prognostic Scoring Systems in Tetanus Phillips Score

Factor	Score
Incubation Time	
< 48 hours	5
2-5 days	4
5-10 days	3
10-14 days	2

Complicating factors	
Injury or life-threatening illness	10
Severe injury or illness not immediately life-threatening	8
Injury or non-life-threatening illness	4
Minor injury or illness	2
ASA Grade 1	0
Total Score	

The diagnosis of tetanus is clinical for the most part. The WHO definition of adult tetanus requires at least one of the following signs: trismus or rhisus sardonicus; or painful muscular contractions [6].

To manage this condition: isolation in a dark and quiet room, with heavy sedation and muscle relaxant administration to prevent spasms. Benzodiazepines are most commonly used; it's favored for its combination of antispasmodic, muscle relaxant, anxiolytic and sedative effects, which are particularly useful for tetanus patients. Diazepam modulates GABA-A transmission and increases presynaptic inhibition. Dantrolene is a muscle relaxant that is effectively used in the treatment of malignant hyperthermia and neuroleptic malignant syndrome [9]. Studies have proven that magnesium sulfate has significant efficacy in the management of autonomic symptoms [10].

Antibiotics are also administered in tetanus, penicillin, and metronidazole being favored. It reduces the proliferation of the bacteria at the inoculation site.

For neutralization of circulating toxin, tetanus immunoglobulin is used. There is no certified fixed-dose; for prophylaxis in susceptible wounds, it is 250 IU of TIG administered intramuscularly For active tetanus case a dose ranging from 3000 to 60000 IU may be administered, 500 IU at a time [11].

Recurrent tetanus is a possibility as infection does not provide immunity to subsequent infections [12].

Tetanus being a potentially fatal disease, the medical fraternity must emphasize its prevention rather than its treatment. Despite it being an “old world” disease, it is surprisingly prevalent in India, along with the other developing nations. This could be attributable to many factors, such as inadequate knowledge of wound hygiene, irregular immunization, lack of awareness on what the disease is, and how fatal it can be, unequipped health centers, unavailability of vaccine, etc. However, the annual mortality rate per 100,000 people from tetanus in India has decreased by 86.3% from 1990 to 2017 [13]. We are doing this study to understand the clinical profile of tetanus in our region.

MATERIALS AND METHOD

This is a retrospective hospital-based study done during the year 2017-2019 in Epidemic Diseases Hospital, Bangalore. All the cases presenting to the hospital and which were diagnosed with tetanus were included in the study. The patients who were started on treatment and then referred to the hospital were excluded from the study.

The patient’s demographics and clinical data were collected and compiled in an excel sheet and analyzed. The patient data which was collected maintained patient confidentiality throughout.

RESULTS

The total number of patients who meet the inclusion criteria were 58 cases. The majority around 87% of the cases presented from the rural area and 13% were urban areas. The sex distributions were 35 males and 23 females. The majority of the patients were in the age group of 55-60 years; the minimum and maximum age being 5 years and 89 years respectively.

The average duration of hospital stay was 15 days, the minimum duration being 1 day and the maximum is 45 days. Out of these cases, Discharge against medical advice was done in 11 cases due to patients stating personal reasons.

The site of injury was an injury to the foot in 65% of the patients, followed by injuries to the fingers or the hand in 30% and 5% were cases of injury due to tooth picking with a pin, splinter removal using pins. Out of the injuries which occurred, the majority of them happened in agriculture fields summing up to 70%; and 10 % were from carpentry works; 10% due to fall/trauma/accidents.

In 25 cases the wound was noted and in the others, it was a healed wound.

The mean incubation period was around 14.5 days from the time of injury to the development of symptoms in the patients who survived. Totally 14 deaths noted, the cause of death was a late presentation to the hospital, taking alternative medicine treatment; ignorance also contributed to delayed presentation to the hospital. The fatal cases also had multiple comorbidities like type 2 diabetes mellitus, hypertension, almost all the cases were in the age group of 65-75 years. The progression of illness was rapid and they passed away within 5 days. The patients with nil comorbidities have a better chance to recover. Overall 36 patients had NIL co-morbidities. 95% of death cases hadn’t received tetanus immunoglobulin.

During the initial presentation of symptoms:

- lockjaw/inability to open mouth: 41
- neck stiffness/pain: 25
- difficulty in walking: 2
- limb pain/stiffness: 17
- back muscle pain/stiffness: 12
- dysphagia: 7

Towards the peak of the diseases, most of the symptoms were present for all the patients.

72% of the cases were noted to have autonomic dysfunction like fluctuation in pulse, blood pressures, sweating, and altered respiratory pattern on and off, postural fall of BP.

DISCUSSION

After compiling the epidemiological and clinical profiles of these patients we concluded that in a majority of the cases, the disease was introduced via injuries sustained in agricultural fields. This is in accordance with a paper published by Arijit Sinha, Bikash Chandra Seth et. In this study, they found that 81.34% of their patients hailed from rural areas [14]. The agricultural population constitutes a major part of the country’s society, therefore we must focus on preventative and awareness promoting methods to significantly reduce the risk as well as improving prognosis.

Another inference reached was the predisposition of tetanus to develop in males; according to our study 35 of the 58 cases were male which comes up to 60.34%. This is in line with a study conducted by Anuradha et. al [2].

Both of these inferences can be explained by the fact that the male population of the lower socio-economic strata who spend most of their day in the fields will inadvertently be at much higher risk of acquiring tetanus. Also, the female population whose attire covers more body surface, are additionally protected by the antenatal dose of tetanus vaccine that they receive as part of the routine immunization schedule prescribed by the government. These factors, along with the generally lower frequency of going into the fields, put them at lesser risk compared to men.

In the study conducted by us, it was also found that the majority of the patients were in the age group of 55-60 years. This is in accordance with the studies done by V G Marulappa [15] and Chalya et al. [16] which concluded that the majority of patients were above 40 years old.

Another finding of the study we conducted was that the average duration of hospital stay was 15 days, which is almost in accordance with to study done by S Chaudhary in which the mean duration of hospital stay was 12 days, ranging from 1-32 days [17].

In the collected data of patients presenting to our hospital, the site of injury the foot in 65% of the patients. This could be because field workers and people in rural areas do not use adequate foot protection when working in the fields or elsewhere and thus are more susceptible to sustaining tetanus prone wounds. This is in accordance with the findings of other studies [14, 17, 18], one being a paper by K.V.L. Sudha Rani [18] in which 79% of the cases included in their studied involved wounds on the lower extremities.

In 25 cases the wound was noted and in the others, it was a healed wound. In other studies however it was noted that commonly they presented with acute forms of injury rather than old ones [18,19]; in a study by V G Marulappa, they recorded that 47.9% of their patients presented with acute trauma, with 14.6% presenting with older wounds [15].

The mean incubation period was around 14.5 days from the time of injury to the development of symptoms in the patients who survived, which is in accordance with other studies conducted, the study conducted by AHM Feroz et al reported it to be 10.8±2.1 days with a range of 3-28 days [18].

According to the compiled data of the clinical presentations of the cases that came to the hospital, the most common presenting feature is lockjaw, i.e. inability to open the mouth, which was present in 70.68% of the patients. The others were neck stiffness and pain (43.1%), limb pain (29.3%), back pain (20.68%), dysphagia (12.06%), and difficulty in walking (3.4%) in decreasing order of frequency. This is in line with the findings of a study by Pornchai S in Thailand, in which 87.2% of the cases had presented with trismus [20]. Other studies also infer trismus to be the most common presenting feature [14, 21]. In a study conducted by Muhammad Saleh Khakheli et al., they reported patients to be clinically diagnosed with tetanus if they had the following symptoms- trismus, neck or abdomen rigidity, and reflex spasms; and were accordingly classified as generalized or cephalic tetanus [22]. According to a study carried out in Pakistan by Mahsud I U et.al, the most common symptoms tetanus patients presented with were lockjaw, dysphagia, and trismus [23].

Out of the 58 cases, 14 deaths were noted, which sums up a case fatality rate of 24.1%. Other studies yielded similar values, for example in a study conducted in Ethiopia by Amare A. they had a case fatality rate of 27% [24]. In a study conducted in Solapur by A B Pawar el at., they found that in 26.3% of the cases complications such as respiratory failure, cardiac arrest, septicemia, etc arose, and in those with complications, there was a 75% fatality [25]. Autonomous complications have been reported in various other studies which significantly worsened the prognosis [1, 26]. Case fatality can be attributed to several factors, such as the presence of comorbidities, advanced age, the degree and mechanism of the wound, the time of presentation, lack of awareness of preventative measures, and immunization. 95% of the fatalities had never received immunoglobulin. Also, mortality would seem to be inversely proportional to the duration of the incubation period according to various studies [27, 28, 29].

72% of the cases were noted to have autonomic dysfunction like fluctuation in pulse, blood pressures, sweating, and altered respiratory pattern on and off, postural fall of BP. In other studies also autonomic dysfunction was found to be a frequent complication [18, 30]. In a paper in which the study was carried out in Mysore, it is reported that most of their cases too died as a result of cardiorespiratory arrest [15].

Out of the total number of patients, 11 of them went DAMA, i.e. had to be discharged against medical advice. This could be due to several reasons. A simple lack of awareness as to the seriousness of the condition, financial constraints, customs and beliefs, faith in alternate methods of non-medical treatment, etc, etc. The only way to minimize such cases is to make admission financially more feasible, increase the availability of immunoglobulin, ensure the adequate counseling of patient and attenders, and to spread awareness in the community as to how this disease must be treated at a fully equipped hospital, as well as the potential fatality of the disease.

CONCLUSION

Tetanus is a treatable disease if there are timely precautions and interventions, such as taking tetanus toxoid injection, followed by Tetanus immunoglobulin and wound care. Through our study, we want to promote awareness among the doctors about the current situation of tetanus and emphasize that it's a still ongoing and ever-prevalent problem and we have to address it by working together. We need to create awareness among the general public regarding basic wound treatment, the prescribed immunization schedule. We must also emphasize the symptoms and signs of the disease to them so that they may identify it early and allow for timely intervention, which significantly improves the prognosis. Most of all, it needs to be made known to the public that this is an ailment, that if left untreated, has a very high chance of fatality and must not be underestimated.

Disclosure statement

This is a retrospective study, where there was no involvement of any human subject or any intervention, it was just an observational study, and only data collected from the case sheet was done and patient details were kept confidential at all times.

The institutional ethics committees approved was this research complied with acceptable international standards (such as the Declaration of Helsinki)

In memoriam – Brigadier General Mihai Nicolae Bînă

Dan Mischianu[1]

Now, in February 2017 as I write this, I find it appropriate to revive the dormant memory of the reader to remember about Prof. Mihai Nicolae Bina, MD.

The future General, Physician and Professor of Urology Mihai Nicolae Bina was born on April 2, 1942 in the city of Craiova and passed away on the day of Saturday, March 3, 2012, when he still had certainly much to say and decide in our profession.

He did not like to remember and to celebrate his birthday, because, unfortunately, he had lived in his youth, as a medical student, a memorable drama: on the day of April 2, on the same ward of the Central Military Hospital, in the same clinical unit which, over the years, he will lead with professionalism, skill and dedication, his mother died – the distinguished professor Olimpia Bina. I remember that sometimes on the eve of that day, he avoided to enter in that reserve.

His father, General Professor Nicholas Bina, was a distinguished professor at the Military Academy ("Carol I" National Defense University, new style).

He came, therefore, from a family with an application for the study and the profession of arms so that, from the outset, the stars lined up to become an excellent professional of military medicine.

After graduating "Dimitrie Cantemir" high school from Bucharest, in 1959 he became a student of the Faculty of Medicine of the Medical and Pharmaceutical Institute in Bucharest and also the "pupil" of the Medico-Military Institute (this was the denomination for those who do not know). He once told me with sorrow and frustration as he went, in boots, from the Military Medical Institute Street near North railway Station to the college. There were incomprehensible times...

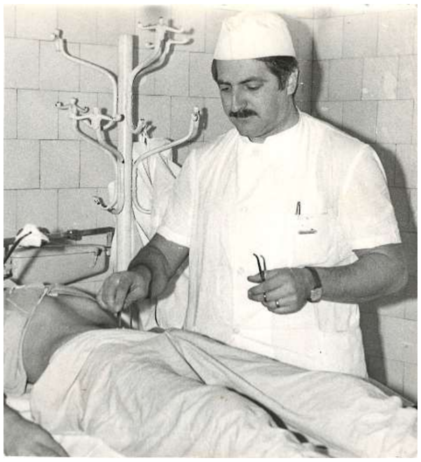
He completed his university studies, he graduated first of his generation in 1965.

His professional excursus was, from the outset placed under the best possible circumstances and almost obvious under today's ARU slogan: "Labor omnia vincit improbus" – Virgil, Georgice.

He was "extern" by competition (1963-1964), "intern" by competition (1964-1967), a brief period of teaching assistants at the Military School in Focsani, then secondary physician urologist, managed with the highest scores in the country.

---

[1] Carol Davila University
Central Emergency Military
Hospital, Bucharest



I got to make a confession.

Military doctors came, then and now from the same "strain" – the School of General Professor Carol Davila. After the Second World War, given the times and their understanding and approach their respective professional elite, felt, certainly some frustration in relation to their "civil" academic peers.

This "embarrassment" was not shared by the elite of the Romanian military medicine: Generals dr. Ion Atanasiu, Scarlat Longhin, Iuliu Şuteu, Gheorghe Niculescu, Traian Oancea, Academicians Victor Voicu and Ioanel Sinescu and many others, which through perfect and fair relationships with civilian colleagues have proven their worth and have integrated in the academic medical landscape of Bucharest as an unshakable symbiotic part. Future General Professor dr. Mihai Nicolae Bina had the same status!

Dr. Mihai Nicolae Bina became a specialist urologist (1971-1979) and consultant urologist in 1979 in one of the last competitions of its kind conducted in Communist Romania, because, then things have broken down altogether.

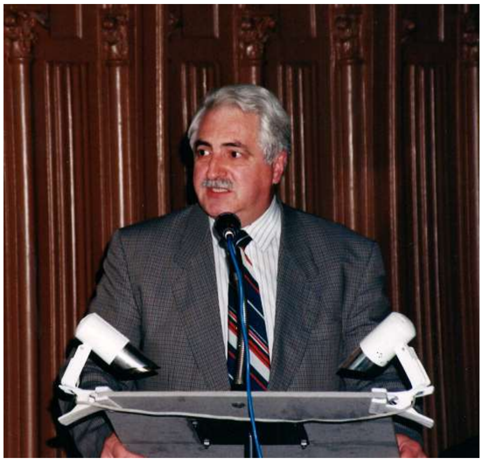
In fact, until 1991 the contest for "primary physician"/ consultant (new style!) was no longer conducted.

After a brilliant internship in general surgery in which he learned much and already mastered this "type" of specialty he confessed with some nostalgia the "impact" it had on him the first "seen" prostatectomy in Fundeni Hospital which was performed by his first urologic "mentor" – Professor Dr. Gheorghe Olanescu. Particularly bleeding, not followed by rigorous hemostasis as in abdominal surgery, continued by placing a hemostatic mesh, he seemed quite marked after three decades by this motivational experience.

Professor Bina was, and has been throughout his terrestrial existence, a great fighter.

And to dispel the "embarrassment" that we mentioned earlier he elaborated under the leadership of Professor dr. Docent Valentin Neagu – incomparable personality of Romanian urology (2017 is the 100th anniversary of his birth: who knows this?) his hard worked PhD thesis, entitled 'Readjustment of the upper urinary tract after dezobstruction of the bladder neck in benign prostate hyperplasia" – held in 1976.

In 1979 he became consultant urologist.



Meanwhile, in an absolutely dumb decade, he had carried out studies of “Emergencies in Urology" and "Urologic Oncology" (1979), under the mentorship of the Academician Eugen Proca and an International Course for young military doctors (Macolin, Switzerland), which he told me about often.

Post-revolutionary era found him prepared for future missions. He was the head physician of Clinical Urology Department of the Central Military Hospital between December 1990 and November 2004.

I was a doctor on duty on the day of November 30, 1991 when, he arrived from the Ministry of Defense, and he told me that on December 1, 1994 will be raised to the rank of Brigade General. I kissed him on both cheeks and I was proud that urology in this regard has its continuity.

This is a unique moment in the life of a man – after a lifetime of work and struggle.

This memory can certainly be connected to those written by the great writer Marin Preda, in a novel, once: "What has meaning for a civilian, for a soldier has a totally different one!"

In 1994 he accomplished his universitary dream: he became Senior Lecturer and later, in 2000, Professor of Urology of the Department of Urology, Faculty of Specialization and Training, Medico-Military Institute, University of Medicine and Pharmacy "Carol Davila" Bucharest.

Since 1995 he was a member of the Academy of Medical Sciences.

As I wrote five years ago in an ever undesirable "In Memoriam": "Hollow data fail to surprise and to outline the man that was Mihai Bina".

At Professor Mihai Bina I think everyone who knew him admired his sharp observation spirit, his gentleness, surgical talent, intelligence and diligence in all that which he has undertaken in earthly life.

Without Professor Mihai Bina, without his delicacy when advising or criticizing, without his professional experience and humanity, life looks very sad!...

To me, I confess, the work effort and way of thinking of Professor Mihai Bina was an example and an impulse.

Innovative solution for SARS-COV2 epidemic management

Silviu Stanciu[1], Magdalena Gurzun[1], Diana Iancu[1], Valeriu Gheorghita[1], Cristian Lupascu[2], George Gugulea[2], Armand Ropot[2]

Abstract: *The SARS-CoV-2 pandemic challenged the authorities into taking measures that limit the spread of the virus in the community. TAMEC project (Advanced Community Approaches to Epidemic Management) developed a system that detects the contacts of patients infected with the SARS-CoV-2 virus and alerts them using mobile applications. It allows real-time analysis of confirmed patients and identified contacts, early detection of new outbreaks, and provides decision-making information to prevent viral transmission. The system uses its patent for homomorphic encryption, a method that allows to process and manipulate data in an encrypted format, without having access to the original data. Thus, the solution proposed in the TAMEC project fully respects the privacy rules of citizens imposed by the EU, using the concept of privacy preservation. Our solution offers the possibility to identify and validate a risk score that could become an extremely helpful tool in the stratification of COVID-19 patients. The TAMEC system is innovative in its simplicity and ability to facilitate the prevention of the spread of the SARS-CoV-2 virus in the community*

Keywords: *SARS-CoV-2 virus, prevention, privacy, artificial intelligence*

The SARS-CoV-2 virus pandemic challenged the authorities into taking measures that slow and control the spread of the virus and limit the disease among the population. Prompt identification of contacts and possible outbreaks is essential so that normal activities could be resumed. Researchers from Google and Oxford [1] concluded that if 15% of the population would benefit from a digital alert system, the number of infections and deaths could be reduced by 8% and 6%, respectively. Their studies concluded that 90% of people alerted would voluntarily start quarantine for 14 days, with an abandonment rate of 2% per day. One could assume that the benefits would be even greater if the participating population in such a system were more than 15%.

Epidemiological research is crucial in limiting the spread of the SARS-CoV-2 virus. It aims to identify and alert people at risk who have been in contact with confirmed infected patients. Currently, these surveys are carried out by Public Health Care (DSP) employees and include interviewing each infected person. Data collected are used in compiling a list of people in contact with the infected person within a period determined by epidemiologists. Each possible contact is then alerted and informed of the following procedure by a Public Health Care employee (DSP). This is time-consuming and involves significant human resources. Also, the collected data are sometimes incomplete.

Thus, we have developed a system that detects the contacts of patients infected with the SARS-CoV-2 virus and alerts them using mobile applications [2, 3, 4]. It aims to help limit the spread of the disease among the population and to reduce the health care employees' epidemiological research. This system can be extended for use in other

armand.ropot@certsign.ro

contagious diseases, such as seasonal influenza.

An essential part of the TAMEC project (Advanced Community Approaches to Epidemic Management) [5] is the TAMEC Mobile Application which enables the detection and rapid warning of people who had been in contact with patients infected with the SARS-CoV-2 virus. The application provides a high degree of confidentiality for all users' data, thus protecting their privacy [6, 7].

The TAMEC project developed two systems that limit the spread of the virus in the community in two different effective ways:

- TAMEC Mobile System is responsible for early detection and notification of people who have been in contact with an infected person and who are possibly infected with contaminants.
- TAMEC Map System which is a real-time display of the distribution of confirmed cases and possible infected contaminants according to different parameters such as age, gender, profession, geographical location. This system analyses case distribution in different geographical areas and the time evolution of cases in different subgroups. This analysis allows early detection and geographical location of new outbreaks and provides decision-making information to prevent viral transmission.

To date, many such mobile applications rely on collecting location data or interactions of Bluetooth users. These approaches have drawn much criticism and concern for the safety of users' privacy. To solve this problem, the TAMEC Mobile application has been designed using the concept of privacy preservation. Thus, CERTSIGN has used its patent for homomorphic encryption [7]. This is a method that allows a third party to process and manipulate data in an encrypted format without having access to the original data (unencrypted data). This method allows a server to directly evaluate the encrypted data and obtain a result that is also encrypted, without the ability to decrypt the result or initial data. Thus, users will be assured that private information will not be misused, nor accessed without their explicit consent. If a user of the TAMEC mobile application has contact with an infected person, it is entirely their decision to inform the health care employees and to follow specific procedures such as testing or treatment. Also, a user notified by the mobile application as being in contact with an infected person will not be able to identify the infected person, nor the time of contact.

With all measures to secure data and preserve privacy, we are confident that users will be convinced the application is safe. The way the application is launched and promoted might determine the number of people who choose to use it. In addition to alerting the population through a mobile application such as the TAMEC Mobile system, it is also necessary to inform them to increase awareness in combating the spread of the SARS-Cov-2 virus. By knowing the evolution of the virus, one can have feedback and be motivated in adhering to the epidemiological strategies issued by the authorities.

Researchers such as epidemiologists and specialists from public health departments need well-structured and detailed data to determine key factors of the epidemic trend in the community. Accurate, concise, and easy-to-interpret data available for health care specialists enable the identification of outbreaks and risk areas. Thus, the authorities will be able to adopt prompt measures to prevent the spread of the virus from possible outbreaks.

TAMEC Mobile device application uses a system for detecting and alerting the contacts of confirmed infected patients. The system can preserve data privacy, revealing both authorities and users only the minimum information required. The core of this solution is generated by a homomorphic encryption scheme patented by CERTSIGN partner [7], the only Romanian patent of its kind. The system also includes existing digital contact tracing solutions already in use worldwide [8, 9].

The developed system is a modular one that includes six important components, namely:

- TAMEC mobile application. The TAMEC mobile application prototype is dedicated to Android operating system devices with 8 or newer Bluetooth mode versions. The detection of the contact was done using only Bluetooth technology, not GPS location, following the European Commission recommendation published shortly after drafting the project. The mobile app TAMEC is intended to be used by citizens, whom we will also call users. The application allows identifying contacts with confirmed infected patients, with sufficiently good precision in terms of distance and exposure time, using Bluetooth technology available on users' devices. The list of identified contacts that meet the case definition criteria is stored in the phone's memory (14 days for each contact). Periodically, this list is compared to the list of infected people from the Public Health Care System (DSP), using the backend components for anonymization. If a person is identified on both lists, the user is notified, without knowing who the infected person was or when the contact occurred in the last 14 days.
- The DSP web service is a backend component that has the role of ensuring the management of infected people and providing to the Computing Server component the list of

anonymized IDs of infected users. In the case of a production system, this component should be located and managed by the National Centre for Contagious Disease Surveillance and Control/Ministry of Health.

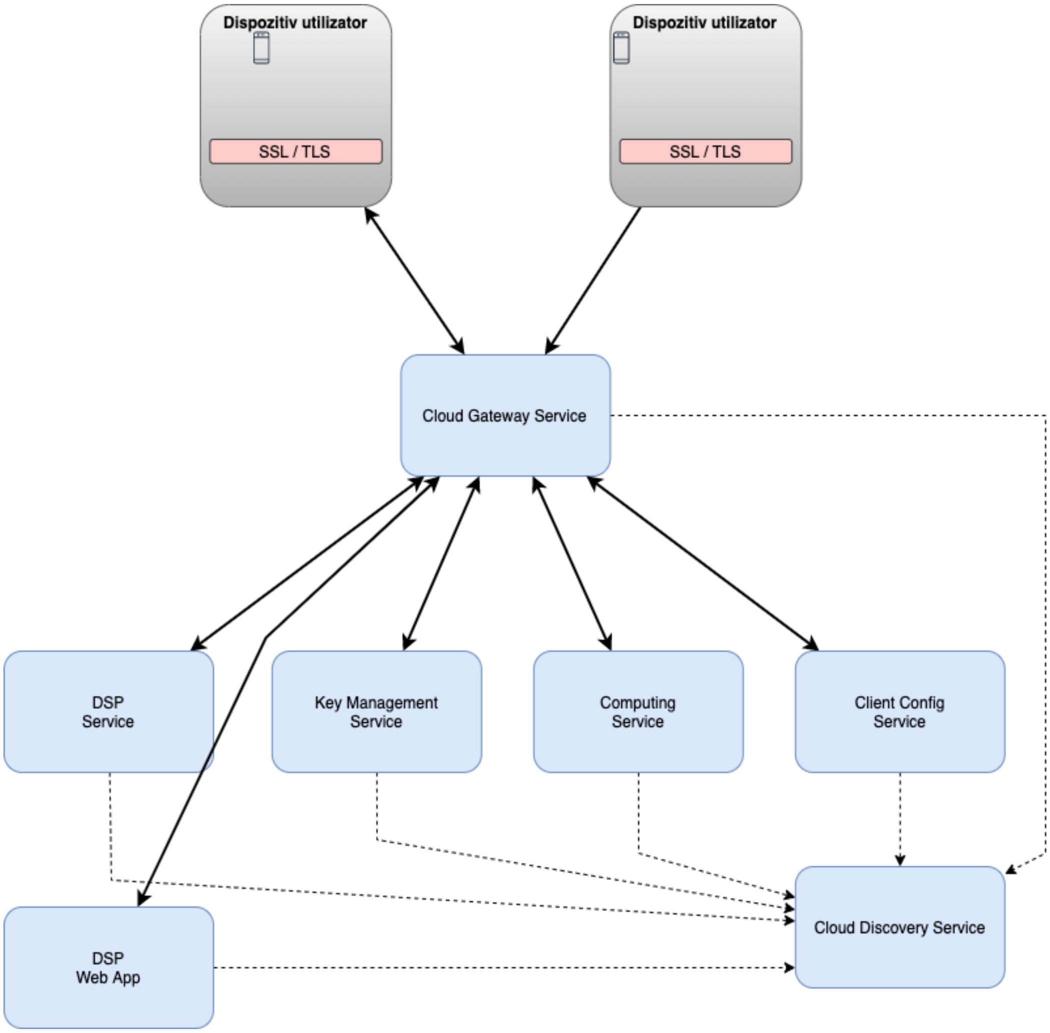
- The KMS web service (Key Management System) is also a backend component that has the role of managing the cryptographic keys necessary to ensure the confidentiality of the data from the system. In the case of a production system, this component should be located and managed by another state entity (e.g. STS);

- CS web service (Computing Server) is another backend component that has the role of performing the cryptographic calculations required by the system, for example, the intersection of anonymized mobile devices users list with the anonymized list provided by the DSP server to identify contacts with infected people. In the case of a production system, this component could be located and managed by a civil entity. This entity has also the role of giving trust to the users and ensuring that no state entity will be able to access, use, and manipulate confidential data of users.

- The CC web service (Client Configuration) is a component of the backend that has the role of centralizing mobile application configurations, depending on the phone type on which it is installed.

- The DSP-WebApp application is a web application that will be used by DSP employees in the territory for contacts management, respectively of the persons notified by the mobile application on the fact that they came in contact with an infected person, and report this and follow the necessary steps (isolation, testing, treatment, etc.). This web application can be hosted by the DSP, even on the DSP server that hosts the corresponding backend component (see the TAMEC Mobile application diagram in Figure 1).

Figure 1: TAMEC Mobile application graphic



- The management system of all confirmed cases and possibly infected contacts detected by the system for detecting and warning the contacts of patients confirmed with SARS-CoV-2, TAMEC Mobile, was named TAMEC Map.

- The developed TAMEC Map system uses the software infrastructure already created in the first phase for the TAMEC Mobile system. The main components of the system are:

- TAMEC Map system database required to present the detailed map with the real-time distribution of all confirmed cases and possibly infected contacts. For each confirmed case or contact this includes the location, form of disease and severity, comorbidities, age, sex, professional category, etc. External data sources are used for this database, such as data available in the Corona-Forms system for confirmed cases, as well as data stored in the DSA WebApp database for contacts. From a technical point of view, the TAMEC Map system database is an extension of the DSA WebApp database developed in the first phase of stage I.

- The graphical interface of the TAMEC Map system is a web application that extends the DSP-WebApp application previously developed with the components necessary for the management and real-time analysis of confirmed cases and contacts and the display of this information, both on a map and in other graphical formats as well. This graphical web interface includes a public area used for dissemination related to the evolution of the pandemic in Romania, as well as a private area used by DSP and MS specialists to analyze the geographical evolution of the virus according to selected parameters, early identification of potential new outbreaks and making the best decisions based on the local situation. This web application can be hosted by the DSP, even on the DSP server that hosts the corresponding backend component.

Geolocations for confirmed or potential cases are obtained from the addresses provided by the Corona-Forms application using a service provided by Google, the Geocoding API. https://cloud.google.com/maps-platform/terms/maps- service-terms # 3.-geocoding-api.

This database is consumed by a graphical interface (called a dashboard) that allows real-time analysis of confirmed patients and identified contacts according to available criteria. Among the information available on this map, a series of necessary data will be identified and counted, such as the location of the diagnosed persons, age group, sex, comorbidities, occupational category, and severity of the disease. This database will not contain personal data of individuals, but only anonymized IDs that can allow only the relevant authority (DSP) to find the identity for a given ID, if necessary. From the graphical interface, it will be possible to easily generate and export reports regarding all the information from the database, depending on the search and reporting criteria. This information can be very helpful for the Public Health Care System to analyze the population epidemic impact for quick and adequate epidemiological measures initialization and to allocate the hospital resources where hospitalization and treatment are required according to medical recommendations.

Also, this type of representation allows real-time mapping of infected population characteristics in each territory, rapid triage, and classification into a risk category according to certain variables (age, sex, associated diseases, stage of disease, pathogenic type of the virus, biological and immunological status of the host). Thus, our solution opens a wide field of epidemiological and clinical research, offering the possibility to identify and validate a risk score that would become an extremely helpful tool in the stratification of COVID-19 patients.

The application also includes tools that allow the dissemination of certain types of reports on social media and indicators that measure their audience.

To conclude, the solution proposed in the TAMEC project is innovative in its simplicity and ability to facilitate the prevention of the spread of the SARS-CoV-2 virus in the community and fully respects the privacy rules of citizens imposed by the EU. The application will allow the development of statistical analysis components, adaptive filtering, and automatic prediction based on artificial intelligence. Starting from the existing information in the system database this can perform their automatic analysis, discover and predict critical developments (e.g. the emergence of new outbreaks), and generate alerts to epidemiologists, accompanied by intervention recommendations.

In-silico evaluation of the potential of a viral protein (Apoptin) as an anticancer agent

Masoud E. Razliqi[1], Ali Najafi[2], Gholamreaza Olad[3], Hadi E.G. Ghaleh[1]

Abstract: *As a significant immunosuppressive virus, chicken anemia virus (CAV) is common among natural poultry hosts and newborn chickens. It contains a tiny single-stranded negative circular DNA genome, encoding three proteins vp1, vp2, and vp3. Apoptin, encoded by the vp3 gene of the CAV virus, is a small protein whose subcellular localization appears to be crucial for tumor-selective activity. Residing in the cytoplasm of normal cells, it translocates into the nucleus in cancerous cells. Apoptin has attracted much attention because of causes specific death in transformed and cancer cells and has toxic effects on cancer cells. In-silico analysis of apoptin revealed the unknown structural and functional features. Physicochemical features and sequence analysis and secondary structure prediction were also conducted using Expasy server tools. Furthermore, the global structure of apoptin was modeled using the I-TASSER server and antigenic features were obtained via the application of the IEBD web tools. The results of in-silico analysis indicated that this protein had a stable structure, was a suitable choice for therapeutic goals, capable of acting as a good anti-cancer agent.*

Keywords: *apoptin; in-silico analysis, chicken anemia virus; cancer*

INTRODUCTION

Cancer is defined as the Irregularity, growth, and proliferation of the cell cycle and sometimes the abnormal proliferation of cells in the body (metastasis). Since the onset of cancer is associated with mutations in some of the natural cell genes, it is considered a genetic disease. Tumor cell mass which is different in appearance and function from normal cells can be either benign (progressive and invasion free with slow growth) or malignant (with rapid growth, metastatic potential), ultimately leading to patient death [1]. Due to the high cost of the medications and cancer treatment facilities, numerous studies have concentrated on finding methods to prevent the disease or effectively treat it [2]. In previous studies, different viruses and their proteins have been used to find a treatment for cancer [3].

Viruses' ability to attach to the cancer cells has attracted the researchers' attention as a novel strategy comparable with conventional therapies, including surgery, radiation therapy, and chemotherapy [4]. The application of recombinant proteins has recently given rise to an interest in understanding and recognizing the physiology of tumor cells. In particular, the identification of these proteins as a new drug and therapeutic cancer vaccine which can use different mechanisms to defeat cancerous cells is crucial for cancer researchers. Unlike prophylactic vaccines, which are generally prescribed to healthy people, cancer vaccines are mostly prescribed to cancer patients. These vaccines are designed to kill cancer cells by boosting the patient's immune response. They kill different immune effects or

mechanisms created by therapeutic vaccination, especially cancer cells and normal cells. The apoptin protein is one of these proteins encoded by the chicken anemia virus (CAV) genome [5, 6].

Infectious anemia virus is one of the most significant immunosuppressive viruses in newborn chicks which are regarded as the natural host of this virus. The virus has three protein sequences as follows: The 50kDa viral protein (VP1) which is the only protein isolated from virus components the 30kDa non-structural VP2 protein functioning as a scaffold protein during the vision accumulations, and the third viral protein VP3 weighing 14kDa, which is located the nucleus of infected cells, but not found in the purified virus components [7]. VP3 is called apoptin, a potent stimulant of apoptosis in and lymphoblastoid cell lines and chicken thymocytes [8]. VP3 gene product due to its apoptotic effect was renamed apoptin [9]. This protein causes apoptosis to be independent of the p53Bcl-2-dependent tumor inhibitor. Apoptosis-induced apoptosis included the induction of caspase, leading to mitochondrial changes and dispersion of cytochrome C [10]. The C-terminal region of apoptin has a bilateral nuclear localization sequence (NLS). NLS1 amino acids from 82 to 88 and NLS2 amino acids remain in the range 111 and 121 [11]. In addition, in the range of 75-107 amino acids, apoptin has a putative nuclear export sequence that transfers the apoptin through the nucleus. Apoptin proteins cause apoptosis in the altered cells (transformed cells), while they leave no effect on normal cells [12, 13].

Bioinformatics refers to the information technology used in molecular biology. Bioinformatics tools can easily identify and predict the primary and secondary structures in a new sequence. This diagnostic tool is applied to find patterns, detect several protein families and show the oligonucleotide primers for a polymerase chain reaction. It also serves as an essential prelude to molecular evolutionary analysis [14]. To the best of the author's knowledge, not much is known about the structural characteristics of Apoptin as an anticancer agent. The main objective in the current study is to evaluate the physicochemical features and determine the secondary and tertiary structure and antigenic features of the apoptin protein of CAV, using bioinformatics tools and databases.

MATERIALS AND METHODS

Sequence analysis

The primary sequence of a given protein (Apoptin) was retrieved from GenBank (ACC. No. AEB91668.1). The first structure of the protein in terms of aliphatic index, extinction coefficient, molecular weight, instability index, isoelectric point, amino acid composition, and half-life in vitro and in vivo are considered as physicochemical features which can be evaluated using various bioinformatics tools.

Physicochemical Features of Apoptin were evaluated using ProtParam, Predict protein, Compute PI/MW tools, and ExPASy server (http://expasy.org). ProtParam database calculated the parameters, such as extinction coefficient, estimated half-life, amino acid composition, theoretical PI, instability index, molecular weight, atomic composition, aliphatic index, and hydropathic mean (GRAVY).

Predict Protein tool can integrate feature prediction for globular regions, B-values, disorder regions, subcellular localization, transmembrane helices secondary structure, intra-residue contacts, structural switch regions, coiled-coil regions, solvent accessibility protein-protein, and protein-DNA binding sites, disulfide bridges, protein-protein, and protein-DNA binding sites, metal-binding sites, domain boundaries, beta-barrels, cysteine bonds.

Structural analysis

The secondary structure components include Alpha Helix, B-Sheet, Turn, Loop, and Coil. The tertiary structure is also formed by the twist of the protein chain caused by the bonding between amino acids which gives rise to functional domains.

Secondary structure was performed to identify Alpha Helix, B- strands, etc, using the Gor, Jpred tools from ExPASy server (http://expasy.org/cgi-bin). According to its amino acid composition and similarity to the sequences of the known secondary structure, the possible secondary structure of a protein can be predicted. RAMPAGE software (http://mordred.bioc.cam.ac.uk/~rapper/rampage.php) was used to determine the validity, stability, and quality of the spatial structure of the protein. Then, the stability of protein structure was evaluated based on the PDB model.

A pattern of comparative modeling was used by the I-TASSER server predicting the third structure based on Homology modeling. I-TASSER provides the biological function of protein molecules from amino acid sequences and the prediction of high-quality models of 3D structure. Energy minimization of the tree-dimensional structure obtained from I-TASSER was performed by the Swiss-Pdb Viewer 4.1.0 software.

Antigenicity

The http://www.iedb.org server was employed to identify antigenic fragments of the protein. IEDB contains experimental data on antibodies and T cell epitopes studied in the fields of infectious diseases, allergies, autoimmunity, and organ transplants in humans and other animal species. Predictions of B cell space epitopes were determined with ElliPro and Discotope servers.

We employed vaxijen server to estimate the antigenicity of the chimeric protein.

RESULTS

Primary sequence analysis

Table 1 shows the results obtained from the Prot param database, the number, and type of amino acids, and atomic components of Apoptin. This protein has 121 amino acids, most of which are Arg and the least are Met and Tyr. The molecular formula of the protein is C566H945N179O180S5. The protein's extinction coefficient is assumed to be 1740 if the number of cys is reduced to 1490. The protein's extinction coefficient is calculated using the amino acid composition (Table 1) of the protein. The estimated half-life span in mammals is 30 hours, in yeast 20 hours, and E. coli 10 hours. The protein instability index was calculated at 68.45.

The aliphatic index of protein was 65/37. The hydropathic mean (GRAVY) was also estimated to be -0.748

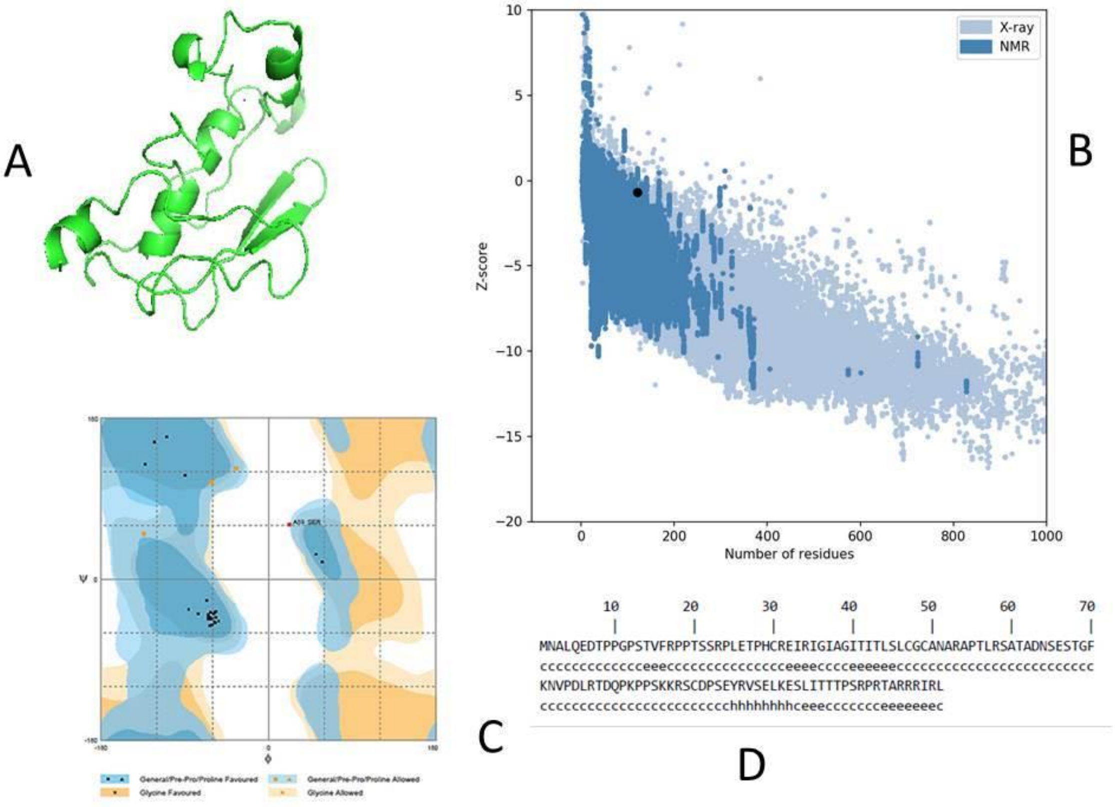
Table 1: Proteins parameters database

Number of amino acids	**121**
Molecular weight	13298/12
Theoretical pI	10/05
Formula	$C_{566}H_{945}N_{179}O_{180}S_5$
Total number of atoms	1875
Estimated half-life	30 hours (mammalian reticulocytes, in vitro)
	>20 hours (yeast, in vivo)
	>10 hours (Escherichia coli, in vivo)
Instability index	The instability index (II) is computed to be 68/45
Aliphatic index	65/37
Grand average of hydropathicity (GRAVY)	-0/748

The mean pI/Mw was calculated based on the Compute PI/MW database (PI=10/05, MW=13298/12)

According to the Ramachandran map obtained from RAMPAGE software, the protein is the apoptotic protein (Figure 1).

Figure 1: A (Image of 3D forms of the apoptin protein obtained from the i-Tasser database). B (prosaweb result). C (Image depicts the Ramachandran map of apoptin protein). D (Indicates the composition of the secondary structure of the protein)



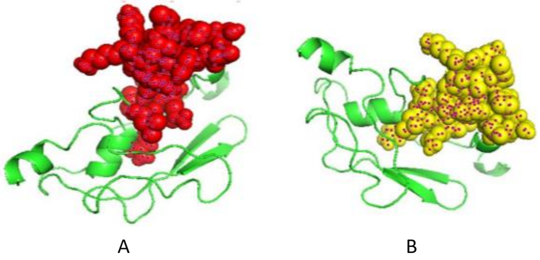
Prediction of tertiary structure

As shown in Figure 1, i-Tasser protein simulated models were calculated quantitatively by a C score based on the importance of pattern rules and convergence parameters of the structure assembly simulation. The energy minimizer of apoptin protein was obtained by using simulated models by the i-Tasser database in spdbv software indicating that apoptin is a stable protein.

Prediction of linear and discontinuous epitopes

According to Figure 2, the spatial structure of apoptin was obtained from the IEDB database, predicting an antigenically active peptide in the apoptin protein.

Figure 2. A (The Linear Epitopes spatial structure obtained from Ellipro). B (Discontinuous Epitope)



DISCUSSION

CAV is a small non-enveloping virus that has a single-stranded circular DNA genome measuring 2.3 KB. The major structural protein (VP1) of viruses is encoded by the genomic strand, while at least two other proteins (VP2 and VP3) are encoded by the antigenomic strand. VP3, called apoptin, is a non-structural protein made up of 121 amino acids. Apoptin contains some residues of proline, serine, and threonine and has a positive charge at the C- terminus [15].

Apoptin protein induces apoptosis just in altered cells (cancer cells) but does not affect normal cells. The specificity of the effect of Apoptin depends on its location in the cell. Its transfer from the outside to the nucleus of the cell in the attachment process to the cancer cells increases its specific effect compared to other normal cells. This protein, in cancer cells, is located in the nucleus and regulated by phosphorylation. Apoptin can induce specific apoptosis of tumor cells in a p53-independent pathway. Apoptosis is moderated by intracellular cysteine proteases (caspases) as the initiator and executor of the apoptosis process [16].

Zhuang et al. indicated that apoptin is capable of inducing apoptosis in human osteosarcoma cells. Subsequent studies found evidence that apoptin induces apoptosis in various human hematologic tumor cells. Also, another study on the effect of apoptin protein by bacteriophage carriers on human breast tumor cell line (BT-474) showed that it influences the cancer cells, while it has no inhibitory effect on normal cells [8].

Traditional laboratory-based cancer research consists of costly experimental trial and error strategies applied to humans, animals, and their harvested tissues. “In-silico experimentation,” combines computational technologies with the mathematical or theoretical properties of cancer bio cells and presents a new approach to advancing cancer treatment [17].

This study showed a simulated 3D model of apoptin generated by using homology modeling as a backup alternative to the conventional, crystallography- or NMR-based methods. In addition, bioinformatics tools for different purposes such as primary and secondary structures and computational modeling of protein structures can help predict new choices for cancer therapy [18, 19].

The results of physicochemical features of apoptin protein including instability index, GRAVY index, solubility index, and aliphatic index evaluated by Prot param database help predict desirable apoptin protein. Since no 3D structure has been identified to date, the present study aimed to evaluate the structure of apoptin using the I-TASSER server. The results stored in pdb were assessed for stable and appropriate energy conditions by Swiss-Pdb Viewer 4.1.0 software, and then energy minimization was analyzed. The image obtained from the server along with the prediction results compared to the Ramachandran graph prediction generally showed structural stability as a fusion protein. Lee et al. (2012) demonstrated that direct engineering of apoptin protein was a suitable and cost-effective strategy to enhance the expression of TAT-Apoptin protein in E. coli [20].

Despite having drawbacks targeting only one epitope or several epitopes of tumor-associated antigen (TAA), protein/ peptide-based vaccines are more cost-effective than autologous or personal vaccines. It is believed that the induction of antigen-specific CTLs and antigen-specific helper CD4 + T cells is essential for the optimal efficacy of the cancer vaccine. Some polypeptide vaccines (eg, Stimovax) potentially contain the CD4 and CD8 epitopes. Altering the peptide sequence of TAAs to introduce agonist-boosting epitopes is another method to increase the immunity of its antigen, which enhances the binding of the peptide to the MHC molecule or T cell receptor, resulting in a higher T cell response and/or T cells with higher or higher power [21]. In the present study, epitope mapping apoptin showed that this protein can be an appropriate candidate for therapeutic cancer vaccines.

To the best of the authors' knowledge, not much is known about the structural characteristics of apoptin. The main objective of the current study was to assess the potency and specificity of small apoptin protein in cancer therapy. However, more studies are needed for designing new small apoptin-like peptides to improve the anti-tumor activity of apoptin and avoid their undesirable side effects.

CONCLUSION

As the in-silico results indicate, apoptin has a stable structure and can be regarded as a suitable candidate for cancer treatment. Furthermore, the appropriate structure of apoptin may lead to its selection as a therapeutic cancer vaccine capable of stimulating both the humoral and cellular immune systems.

REVIEW

Intention to vaccinate against COVID-19 in patients with autoimmune diseases

Elisabeta Candrea[1], Cristina Pamfil[1], Jeno L. Vargha[2], Maria Crisan[1], Adrian Baican[1], Adrian Neacsu[3,4], Roxana M. Toader[5], S. Rednic[1]

Abstract: *Understanding COVID-19 vaccination attitudes is of paramount importance in order to estimate and influence the willingness to vaccinate.*

A cross-sectional study was performed in the spring of 2021 in Romania by sending a web-based questionnaire to patients with rheumatic autoimmune diseases in order to assess their willingness to vaccinate against SARS CoV-2 and to identify factors that might influence their decision. Variables derived from the questionnaire were analyzed in univariable and multivariable analysis.

71 patients, of which 60 (84.5%) women, were included in the study, with a 53.5% (38 subjects) willingness to vaccinate. A positive association was observed between the willingness to vaccinate and the patients' trust in authorities, trust in the healthcare system and the choice of scientific sources of information in their decision making. A positive correlation was observed between the intention to vaccinate and the global VAX score, as well as the subscale VAX scores (p<0.05). Global VAX score emerged as a predictive factor for the intention to vaccinate on logistic regression (p<0.05).

The present study underlines the importance of reliable scientific sources of information for pa-tients with autoimmune diseases and how the general attitude about vaccination becomes a pre-dictive factor for accepting COVID-19 vaccine.

Keywords: *COVID-19, vaccination, autoimmune diseases*

INTRODUCTION

The SARS-CoV-2 infection accounts for a high morbidity and mortality, having caused the death of more than 3 million people all over the world since the onset of the pandemic [1]. The COVID-19 disease particularly endangers people with comorbidities, leaving patients with autoimmune diseases in a place of uncertainty and vulnerability, enhanced by the fear of an increased risk for infection in the context of immunosuppression.

The current increasing prevalence of coronavirus worldwide will unfortunately provide the necessary data on the follow-up of autoimmune conditions. From an endocrinological point of view, patients with autoimmune thyroiditis have a higher risk of developing other antibody-related conditions such as vitiligo, alopecia areata, dermatitis herpatiformis, hypophysitis, autoimmune hepatitis, Sjogren's syndrome, Raynaud's syndrome, premature ovarian failure, primary adrenal insufficiency, type 1 diabetes mellitus, rheumatoid arthritis, atrophic gastritis, lupus, sclerodermia, vasculitis, and celiac disease [2].

The rapid development of vaccines against the SARS-CoV-2 infection provides the opportunity of acquiring immunity without the need of going through the disease. However, the novelty of the vaccine and of the technological platforms were paralleled by a gap in knowledge regarding the potential side effects of vaccination. Patient with autoimmune diseases thus struggled in a battle where on

one hand was the desire for protection against a virus that might aggravate a serious, chronic disease and, on the other hand, was the concern regarding safety associated with vaccination. In this light, our aim was to assess the intention to vaccinate among patients with rheumatic diseases.

MATERIALS AND METHODS

A cross-sectional study was performed in the spring of 2021 in Cluj-Napoca, Romania. A web-based questionnaire was sent via a Google docs platform to patients with autoimmune diseases before a patient-dedicated virtual event, in order to assess their willingness to vaccinate against SARS CoV-2 and to identify factors that might influence their decision.

The questionnaire comprised a small section dedicated to general data, including a personal and family history of COVID-19 infection; a section evaluating the anxiety regarding COVID-19 as elaborated by Lee [3], a section evaluating the general attitudes toward vaccination, addressed by the means of the Vaccination Attitudes Examination (VAX) scale, developed in English by Martin and Petrie [4] and validated in Romanian by Huza [5]; VAX scale is comprised by the following four subscales: mistrust of vaccine benefit, worries about unforeseen future effects, concerns about commercial profiteering and preference for natural immunity.

Supplementary questions regarding the attitudes of patients towards the government, healthcare system and guideline compliance were imported from an article that published the data of the UCL COVID-19 Social Study [6]. One question evaluated whether the decision to accept the COVID-19 vaccine was due to information drawn from non-scientific sources (the opinion of a public person, opinion of friends, possible travel restrictions, others) or from scientific sources (scientific books and journals, opinion of an expert in the field).

Participants received no compensation for completing the questionnaire, however, they had enhanced access to communicate with the physician to address further inquiries regarding their autoimmune pathology or COVID-19 disease, including vaccination.

For the statistical analysis, variables were derived from the questionnaire and included in a bivariate analysis. Chi square test was used to assess the relationship between the intention to vaccinate and most of the variables considered for analysis. Fisher test was used to assess a relationship between the intention to vaccinate and COVID-19 guideline compliance and Freeman-Halton test for the variables type of immunosuppressive therapy and COVID-19 disease experienced by the subject, the family, close friends and acquaintances. We used Fisher and Freeman-Hallton instead of Chi-Square when the minimum of 5 expected cases was not met, with Fisher being used for 2x2 matrices and Freeman Gallton for 2x3 matrices. Significance threshold was considered under 0.05. Multivariable analysis was subsequently performed by the aid of logistical regression. Statistical analysis was performed using SPSS v21.

RESULTS

Of 75 answers that were submitted, 71 were included in the study after a quality control check. The study sample consisted mostly of women, 60 (84.5%), participants having a mean age of 46 years, mostly from urban areas 58 (81.68%), with various autoimmune diseases, such as dermatomyositis 4 (5.6%), systemic lupus erythematosus 13 (18.3%), rheumatoid arthritis 28 (39.43%), systemic sclerosis 12 (16.9%), Sjogren syndrome 3 (4.2%) and other autoimmune diseases 13 (18.3%). The diverse forms of autoimmune diseases necessitate diverse treatments, ranging from hydroxychloroquine 10 subjects (14%) and biologic therapies such as belimumab, rituximab, tocilizumab 7 (9.8%) to other immunosuppressive drugs such as prednisone, methotrexate, mycophenolate mofetil 54 (76%).

The proportion of patients with autoimmune pathology willing to get vaccinated was 53.5% (38 subjects). Upon statistical analysis, a positive association was observed between the willingness to vaccinate and the patients' trust in authorities, their trust in the healthcare system and the choice of scientific sources of information in their decision making ($p<0.05$). A positive correlation was observed between the intention to vaccinate and the global VAX score, as well as the subscale VAX scores ($p<0.05$).

No association was found between the intention to vaccinate and a history of in-fluenza vaccination. Furthermore, the intention to vaccinate was not influenced by a prior vaccination refusal, by the preference for a certain type of vaccine technology (ARN-based, viral vector, inactivated virus or no preference) nor COVID-19-related anxiety.

No statistically significant relationship was noted between the intention to vaccinate and whether the subject or the family/friends of the subject experienced the burden of the COVID-19 disease or whether they are compliant to COVID-19 prevention guidelines recommended by authorities.

Upon multivariable analysis, global VAX score emerged as a predictive factor for the intention to vaccinate ($p<0.05$).

DISCUSSION

The current pandemic day's prescription is marked by access through digital medicine. The access to investigations might be reduced but drug administration including vaccines should not be postponed, if considered necessary [7]. The willingness to vaccinate in our study (53.5%) was similar to the one reported in a cross-country study (54.2%) with more than 1500 participants with systemic autoimmune or inflammatory rheumatic diseases [8], but slightly lower compared to a willingness of 61% in a cohort of patients with rheumatic diseases in The Netherlands [9].

Our results are significantly lower compared to a 92.9% preparedness for vaccination against COVID-19 in Danish patients with systemic lupus erythematosus and rheumatoid arthritis [10]. The association between pancreatitis, panniculitis and polyarthritis, entitled PPP syndrome, is a special category that need to be included in future studies to see if the percentage is the same like the others categories [11].

The scarcity of clinical trials studying the adverse effects of vaccination on rheumatic diseases, at the time of the study, and the time gap from publication to patient information may be important factors that account for the lack of willingness to vaccinate.

Studies like the one published by Achiron et al [12] revealed the fact that disease relapse in another autoimmune disease, multiple sclerosis, was similar in patients compared to controls; the rates of adverse events was higher in younger patients and in subjects with lower disability, orienting the physician toward a possible subgroup of subjects that might possibly be at risk of developing unwanted side-effects [13].

Hypercortisolemia found in glucocorticoid osteoporosis is a well known cause of obesity-related type of secondary osteoporosis more frequent in obese subjects without Cushing’s syndrome that display chronic high values of basal cortisol which seems suppressible at dexamethasone inhibition test and the chronic autonomous secretion of cortisol is identified in patients with adrenal incidentaloma with an age-dependent incidence and this has been reported to increase the risk of osteoporosis independent of age, so, this category can be affected by the fear of getting the infection because they are immunosuppressed by their pathology, so the vaccination will be more wished [14].

Data reported in a short-term observational study assessing the safety of SARS-CoV-2 mRNA vaccines in patients with rheumatic and musculoskeletal diseases indicates mainly mild local and systemic adverse events [15,16]. Patients with regression melanomas, a phenomenon that occurs as a result of host immune response that attacks the primary melanocytic tumor cells through lymphocytes determining a fibrotic process, can be also a difficult category of persons that can not wish the vaccination, because they can fear of a faster evolution of the regression and feel the a faster dissemination of the neoplastic cells [17].

Patients with an autoimmune disease are known to have high rates of anxiety and depression [18]. In our cohort, the proportion of subjects with COVID-19-related anxiety was slightly higher than the one obtained from a questionnaire distributed to students enrolled in the healthcare system: 33.8% (24 subjects) vs 28.5% (article submitted). In our sample, choosing scientific sources of information correlated with the positive intention to vaccinate, in agreement with previously published data stating that not relying upon social media for virus information is a significant predictor for the intention to vaccinate [19].

We note that the majority of subjects in our cohort chose scientific resources, 47 subjects (66.19%); this may be attributed to a selection error, participants having been recruited with the occasion of a patient-dedicated virtual event.

In our opinion, the association between the intention to vaccinate and the global VAX score, as well as subscale VAX scores is an important finding since it reveals the way the general attitude toward vaccination influences a particular vaccination choice, in our case the SARS-CoV-2vaccine. The relationship between general vaccination attitudes and the intention to vaccinate against COVID-19 was highlighted in a study having students as a target group (Candrea et al, submitted), but also in a large study involving more than 32.000 participants of various social, ethnical and educational backgrounds [6,20].

The above-mentioned association has a broader impact on the healthcare of patients with autoimmune diseases since they have recommendation for the administration of other types of vaccines, including pneumococcal immunization [21].

Limitations of our study can be considered the psychiatric conditions in these patients, for example the diagnosis of depression as well as the treatment for depression were significantly more frequently associated with psoriasis, an immune mediated disease. Patients with mild psoriasis can experience psychiatric comorbidities; however, depression is more common in patients with severe psoriasis or psoriatic arthritis.

So, father research is needed to se if any psychiatric comorbidities can influence the patient decision to be vaccinated against COVID-19 [22].

In conclusion, the present study highlights the importance of reliable scientific sources of information for patients with autoimmune diseases and shows how the general attitude about vaccination becomes a predictive factor for the de decision to vaccinate against COVID-19. Therefore, it is recommendable to make efforts to shift patients' general attitude toward vaccination.

Intraoperative parathyroid hormone assay in patients with primary hyperparathyroidism

Cornelia Nitipir[1], Lucian Alecu[2], Iulian Slavu[3], Madalina Musat[4], Raluca Tulin[2], Bogdan Socea[5], Adrian Tulin[2]

Abstract: *Introduction: Currently, parathyroidectomy represents the elective surgical treatment and the only one curative that relieves the patient of metabolic complications and improves the quality of life of the patient. Intraoperative confirmation of PTH is required to reflect the fact that the correct parathyroid gland has been extracted. Material and method: The study is retrospective. The period on which the data was gathered over a period of 2 years. The values of the PTH assay were obtained from blood drawn from the ipsilateral cephalic vein of the hyperproductive parathyroid gland: 1. at the moment of anesthesia induction; 2. at identification; 3. at 10 minutes after the extraction; 4. at 20 minutes after extraction. Results: We identified a number of 25 patients operated for primary hyperparathyroidism. Preoperative values of PTH were 380pg/mL with a maximum value of 821 pg/mL. PTH values decreased by 55% at 5 min, 68% at 10 minutes and 74% at 15 minutes. A marked reduction in PTH values occurred after the first 5 minutes while the interval between 10-15minutes associated a variation of only 8-10% decrease.*

Conclusion: Intraoperative PTH assay is a useful technique to predict the success of the intervention. The technique is standard although some issues have been raised and are still under discussion.

Keywords: *PTH, hyperparathyroidism*

INTRODUCTION

The first reported intraoperative dosage of the parathormone or PTH was reported in 1988 by Nassaum et al. [1] The level and the extension of the cervical dissection in patients with primary hyperparathyroidism is still under discussion. In the absence of any preoperative imagistic or laboratory investigations and using only the intraoperative exploration of the parathyroid glands Satava et al. confirmed a rate of succes up to 96% in identifying and extracting the correct parathyroid gland responsible of primary hyperparathyroidism [2].

However, this technique has its limitations which can lead to surgical failure if one encounters a case of multiglandular hyperplasia, multiple parathyroid adenomatous nodules or hyperfunctional parathyroid ectopic tissue.

Primary hyperparathyroidism is an endocrinological disorder commonly found to be produced in 87% of cases by a single adenoma [3, 4]. Hyperparathyroidism associated with the presence of two hyperfunctional adenomas associates an incidence of up to 15% [3, 4].

Currently, parathyroidectomy represents the elective surgical treatment and the only one curative that relieves the patient of metabolic complications and increases the quality of life. To achieve this goal, a minimally invasive

surgical procedure, aimed at a single parathyroid gland that houses the hyperfunctional nodule, is now successfully used, thus replacing bilateral exploratory cervical dissections. This procedure was quickly adopted due to the effectiveness of paraclinical investigations in the field of scintigraphy that allow the exact identification of the parathyroid adenoma during the preoperative evaluation [5].

However, an intraoperative confirmation is required to reflect the fact that the correct parathyroid gland has been extracted. In this regard, the intraoperative PTH dosage is used which due to the reduced half-life of 2-5 minutes coupled with a 50% reduction of the circulating intraoperative values compared to the preoperative values confirms the correctness of the procedure or the opens up the possibility to a cervical exploration to identify other parathyroid glands or parathyroid ectopic tissue [6].

The current protocol involves 4 dosages of PTH: at the time of induction of anesthesia (which will be used as a threshold value) at the moment of identification, at 10 and 15 minutes after the gland has been extracted. Success rates when this technique is used can reach 94% [7].

However, literature has begun to bring into discussion the efficacy of PTH evaluation when multinodular hyperplasia is encountered and the cost-effectiveness of the technique [8].

The study represents a retrospective evaluation of the effectiveness of this technique incorrectly identifying the hyperfunctional parathyroid gland in patients operated in our clinic for primary hyperparathyroidism by a minimally invasive technique.

MATERIAL AND METHODS

The study is retrospective. The period on which the data was gathered over a period of 2 years (01.01.2017-01.01.2019). Data were obtained from the clinic of general surgery of the Clinical Emergency Hospital "Prof. Dr. Agrippa Ionescu," Bucharest, Romania. The following variables were obtained: age, sex, preoperative values of PTH, intraoperative PTH values, postoperative complications, preoperative scintigraphy, surgery time, and length of hospital stay.

The patients were operated using the standard technique of minimally invasive parathyroidectomy.

PTH values were obtained from blood drawn from the ipsilateral cephalic vein of the hyperproductive parathyroid gland: 1. at the moment of anesthesia induction; 2. at identification; 3. at 10 minutes after the extraction; 4. at 20 minutes after extraction.

Laboratory PTH values were obtained using the Radioimmunoassay method.

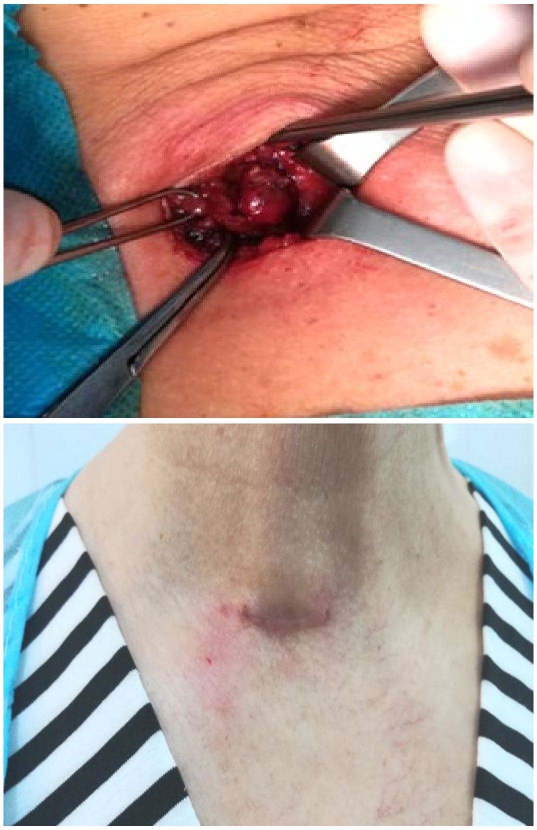
Inclusion Criteria: Diagnosis of primary hyperparathyroidism and surgery for primary hyperparathyroidism.

Ethics: The retrospective analysis of the data has been approved by an Ethics Committee of the institution.

RESULTS

We identified 25 patients, which were operated for primary hyperparathyroidism with a minimally invasive technique on which intraoperative PTH hormone assay was done (Figure 1).

Figure 1: Right parathyroid adenoma operated with a minimally invasive technique – the incision had a length of 5 cm and was focused on the parathyroid gland. The adenoma is clearly visible.



The average age at diagnosis was 54 years with a range of 32-68 years.

The study group was composed of 16 women and 9 men.

A number of 20 patients were diagnosed with singular parathyroid adenoma while multiple glandular adenomas were identified in five patients.

There were no mortalities reported in the studied group. There were no recurrent nerve lesions.

All of the patients were investigated before surgery with Tc 99m Scintigraphy to identify the location of the hyperproductive parathyroid gland. Only three cases did not correctly associate the preoperative scintigraphy with intraoperative exploration.

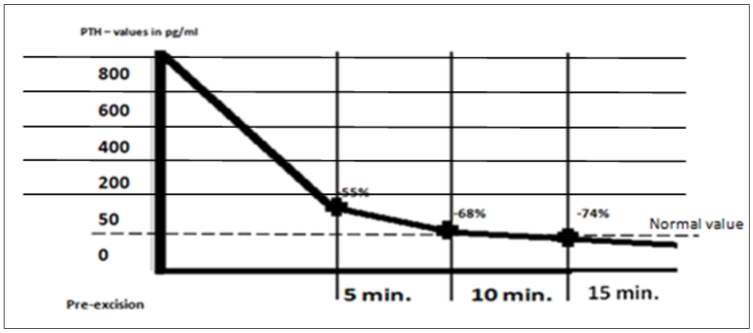
The average hospital stay was 2.3 days while a number of 8 patients were discharged on day 1 after surgery.

All of the patients were operated under general anesthesia.

Average preoperative values of PTH were 380pg/mL with a maximum value of 821 pg/mL.

The mean value (SD) for LVEDV was 144.37 (69.2) ml by 2DE and 143.6 (67.2) ml by 3DE, p=0.8, Spearman's coefficient 0.86. For LVESV the mean value (SD) was 106.26 (59.53) ml by 2DE, 103.24 (55.02) ml by 3DE, p=0.051, Spearman's coefficient 0.85 (Figure 2).

Figure 2: Decrease of intraoperative PTH values after parathyroidectomy at 5 minutes, 10 minutes and 15 minutes



Average PTH values decreased by 55% at 5 min, 68% at 10 minutes and 74% at 15 minutes.

From the above graph, we can observe that a marked reduction in PTH values occurred after the first 5 minutes while the interval between 10-15 minutes associated a variation of only 8-10% decrease of PTH values.

There were no extended lateral cervical dissections done.

Two cases required local explorations by lifting and exploring the posterior region of the thyroid gland. In these cases, the PTH values decreased by 10% in one case at 20 minutes and the other they did not change.

DISCUSSIONS

The methods/techniques one uses to locate the parathyroid gland responsible for hyperparathyroidism has long been a topic of debate. Some surgeons advocate for preoperative investigations such as scintigraphy or cervical ultrasonography while others have fought for bilateral cervical exploration as a standard technique.

Today in order to identify the parathyroid gland, the scintigraphic examination is recognized as the gold standard, while other imaging solutions such as cervical ultrasound allow for a complete examination. Computer tomography and Magnetic Resonance Imaging are widely used to explore the suprarenal gland [9].

Ultrasound and scintigraphy are synergistic. When used together, they achieve a 95% sensitivity in identifying the hyperproductive parathyroid gland [10].

All of these investigations allow for a minimal-invasive targeted approach that translates into reduced hospitalization time, offer the possibility to use local anesthesia and ambulatory surgery, reduced operative time and low failure rates of only 1.5% [11, 12]. All of these advantages have led to a global reduction in costs [11, 12].

Surgical extraction of the parathyroid gland responsible for primary hyperparathyroidism produces a decrease in circulating PTH values thus confirming in real time the success of surgery or indicates towards a rapid change of tactics with the patient still on the operating table and under anesthesia. Failure of primary hyperparathyroidism surgery is largely related to correctly identify the parathyroid gland as it can be confused with lymphatic tissue or thyroid tissue [13].

Another cause of failure is multinodular hyper-parathyroidism, which, in the absence of advanced diagnostic techniques, will force the operator to do a cervical exploration – to identify at least four thyroid glands, extraction of the macroscopically affected glands and to wait for the extemporaneous investigation. This technique associates increased comorbidities and a significant increase in operative time. In literature, so-called false-negative results in intraoperative PTH assay were reported which were due to increased PTH values after extraction of the gland or a delay of up to 30 minutes until the values were reduced. These are mainly due to manipulation of the parathyroid tissue at dissection [14].

No such cases have been encountered in the studied group.

In these situations, the extemporaneous examination of the resected parathyroid gland is of real use. Good communication with the anatomopathological and the laboratory physician is mandatory in order to establish the optimal therapeutic course.

Intraoperative PTH assay has seen its share of discussions. We used this technique with great success and it has proven to be effective in the majority of our surgical interventions. The reproaches are of economical nature, cost-effectiveness and the half-life of PTH, which seems to differ in cases of a single parathyroid adenoma and multiglandular parathyroid hyperplasia. Other issues raised are related to the technique: intraoperative time of PTH harvesting and the PTH value set as the baseline to which a reduction of more than 50% after extraction of the gland is considered effective [15].

Therefore, some authors recommend as the baseline the PTH values from the preoperative day while other surgeons use the PTH value as baseline obtained at anesthesia induction. On the studied group, we used as the baseline the PTH values obtained before induction although some authors consider this value to be 60% higher than the previous day dosing. Subsequent PTH assays after gland extraction showed a 30-40% drop in values and a reduction in of more than 50% at 15 minutes in the cases of correct parathyroid removal.

In cases of multinodular hyperparathyroidism, the extraction of the parathyroid gland can lead to so-called false-positive. In these cases, one can observe a more than 50% reduction in PTH values from baseline although there is incomplete removal of all the hyperproductive parathyroid tissue [16]. To avoid these situations when there is a suspicion of multiglandular hyperparathyroidism, it has been proposed that one should pursue a more than 70% reduction in PTH values from the baseline [17]. A reduction of over 70% of intraoperative PTH values to 10 minutes is associated with healing with a sensitivity of 85% and specificity of 100% (18). When multiglandular hyperparathyroidism exists, preoperative investigations imaging investigations in particular scintigraphy allow for a complete evaluation.

As we observed in our studied group, of great importance is the place where the blood is obtained for the PTH assay. It should be obtained from the ipsilateral cephalic vein of the hyperproductive parathyroid gland. Contralateral blood harvesting delays the decrease in PTH values to more than 10 minutes due to the circulatory time of the hormone. Such contradictory values can raise false doubts as to the fairness of the procedure. In order to increase the sensitivity of the PTH assay, one can harvest blood the upper, middle or inferior thyroid veins [19].

Study limits:

However, the study has limits. It was difficult to appreciate the evolution of the disease until surgery. We could not follow-up, in the long run, the effectiveness of the surgical procedure.

In conclusion, although medical treatment in primary hyperparathyroidism has evolved in time, surgery has remained one of the pillars of treatment. Direct PTH evaluation is a useful real-time technique and can predict utility of the surgical procedure. The technique is standard although some issues have been raised and are still under discussion. As demonstrated in our study a reduction of more than 50% of PTH values when compared to baseline at anesthesia induction can predict the success of the intervention in agreement with the literature. Preoperative scintigraphy plays a key role if one decides to use this technique as it can decrease surgery time and hospital stay.

Introducing two effective techniques for the detection of adenovirus respiratory infection in human sample

Mojtaba Sharti[1], Hadi E.G. Ghaleh[1], Ruhollah Dorostkar[1], Mehdi Tat[1], Ali Razei[2], Alireza Rafati[3], Akbar G. Alvanegh[4]

Abstract: *Recently, respiratory viral infections have witnessed substantial diagnostic evolution, with the advent of emergent pathogenic agents and the improvement of new diagnostic approaches. Acute viral respiratory infection (ARVI) commonly causes illness and fatality, particularly in pediatric patients. Adenovirus has the highest prevalence in upper and lower respiratory tract infections (RTIs) amongst respiratory pathogens of importance. The purpose of this research was to introduce two effective techniques for the detection of adenovirus respiratory infection in Human samples, cell culture, and real-time PCR. Samples from patients aged less than ten years were obtained from Baqiyatallah (as) Hospital and cultured on HEK cells after preparation. After observing the cytopathic effects of the virus, a molecular test (Real-time PCR) with the help of specific primers was done on samples taken from the cell culture. Both assays detected viruses in clinical samples, and results of cell culture and real-time PCR confirmed infection with adenovirus in samples. According to our findings, simultaneous use of tests (cell culture and PCR) based test real-time PCR is a somewhat reliable method for detecting adenovirus in clinical specimens.*

Keywords: *Adenovirus, detection, cell culture, real-time PCR*

INTRODUCTION

Adenoviruses were first discovered and characterized in the 1950s by two groups who searched for the etiologic causes of acute respiratory disease (ARD) [1]. Adenoviruses as icosahedral viruses that have no enveloped with an approximate size of 70-90 nm. The viruses were found epidemiologically to be the main causative agent of ARD in recruited militarians [2]. Human adenoviruses are causing merely a minor percentage of ARD in the general population and for almost 5% to 10% of pediatric respiratory disease. Respiratory tract infections by viruses affect children [3]. Adenoviruses are responsible for epidemic outbreaks in soldiers [4]. In addition to respiratory infection, diseases such as conjunctivitis and infantile gastroenteritis caused by adenoviruses can induce fulminant fatal pneumonia, hepatitis, and/or encephalitis in mankind [5]. The respiratory diseases consist of both upper respiratory (pharyngitis and colds) and lower respiratory (bronchiolitis and pneumonia) syndromes [5, 6].

Around 7% of upper RTIs in youngsters aged below five years result from an adenovirus [3]. The respiratory indications are often associated with systemic demonstrations (e.g., generalized malaise, fever, chills, myalgia, and headache). The usual serovars are Ad 1, 2, 5, and 6 (species C or HA

group III) and, sometimes, Ad3 and Ad7 (species B or HA group I), being indigenous in the majority of populations [7]. Sporadic cases might be indistinguishable from other viral respiratory contagions (e.g., influenza, parainfluenza, and respiratory syncytial virus) [8]. If conjunctivitis comes with the signs and symptoms denoted above, the illness is known as pharyngoconjunctival fever. Ad3 is the adenovirus serovar with the uppermost involvement, but Ad7 and Ad14 isolates among the same HA group have been reported in these patients [9]. Besides, adenoviruses induce lower respiratory tract contagions in youngsters and are a possible cause of nearly 10% of pediatric pneumonia cases [10]. The majority of patients recover from such lower respiratory contagions. However, some pandemics have led to a remarkable fatality, respiratory symptoms duration of almost one week, ocular symptoms for 2–8 weeks, and gastrointestinal symptoms up to 10 days [11]. Adenoviruses are detectable through isolating in nasopharyngeal and conjunctival discharges and throat washes and are visualized via electron microscopic assay of feces in the course of the acute disease phase [12]. Respiratory infections typically represent an elevation in CF antibodies to a common antigen. Virus-related antigens are also detectable in samples clinically through various immunologic methods and PCR [13]. The current research aimed to evaluate the detectability of adenovirus respiratory infections by two techniques, cell culture, and real-time PCR.

MATERIALS AND METHODS

Origin of samples: In this study, samples from patients less than ten years old were received from the Baqiyatallah (as) Hospital and prepared as oral swabs from patients with the common cold and pharyngitis symptoms. In most cases, NP swabs are obtained from elder children and adults, whereas newborns and youngsters are the common sources of NPAs. Since most patients cannot tolerate NP sampling well, other samples were obtained as well. Clinical specimens were transferred to the laboratory on wet ice to preserve viral vitality. These samples were placed in a transport media.

Cell culture: Human embryonic kidney cells (HEK) were cultured in three T25 flasks grown in Dulbecco's altered Eagle medium (DMEM (1X)) complemented with 10% fetal bovine serum (FBS). After inoculation, cell culture tubes underwent incubation at 37 °C and 5% CO2. Samples of patients in the two flasks were inoculated, followed by adding the maintenance medium (DMEM (1X) supplemented with 2% FBS) under the above conditions. Up to a week daily, flasks were examined microscopically to record the viral cytopathic effect (CPE) [14].

Nucleic Acid Purification and Real-Time PCR: A pair of primers were designed for the hexone locus, with forward (5-ACCTGAGTCCGGGTCTGGTGC-3) and reverse (5-GTCAACGGGCACGAAGCGCA-3 primer sequences, as well as a probe sequence of GATGTGACCACCGACCGTAGCCAGCG. Extraction of nucleic acids from respiratory specimens was done by a DNA kit (High Pure Viral Nucleic Acid Kit - Roche) following the manufacturer's instructions. In the next step, a pair of primers was designed for the hexon gene of the adenovirus for specific detection of the virus according to the melt curve. Each reaction had a total volume of 20 µL, including 10 µL of Mastermix PCR probe base, 5 µL of template, 1 µL of primer (0.5 µM), 1 probe (0.5 µM), and 3H2O. The cycling conditions included a primary denaturation step at 95 °C (2 min), followed by 60 cycles (each for 20 sec) at 95 °C, and at 57 and 72 °C for 40 and 30 sec respectively. The annealing temperature was 57°C. A melting curve analysis program was used to identify specific PCR products. After the last cycle, the temperature was increased to 95 °C, then decreased to 75 °C, and slowly elevated to 95 °C at a rate of 0.1 °C per second. Positive and negative controls were added in each set [15, 16].

RESULTS

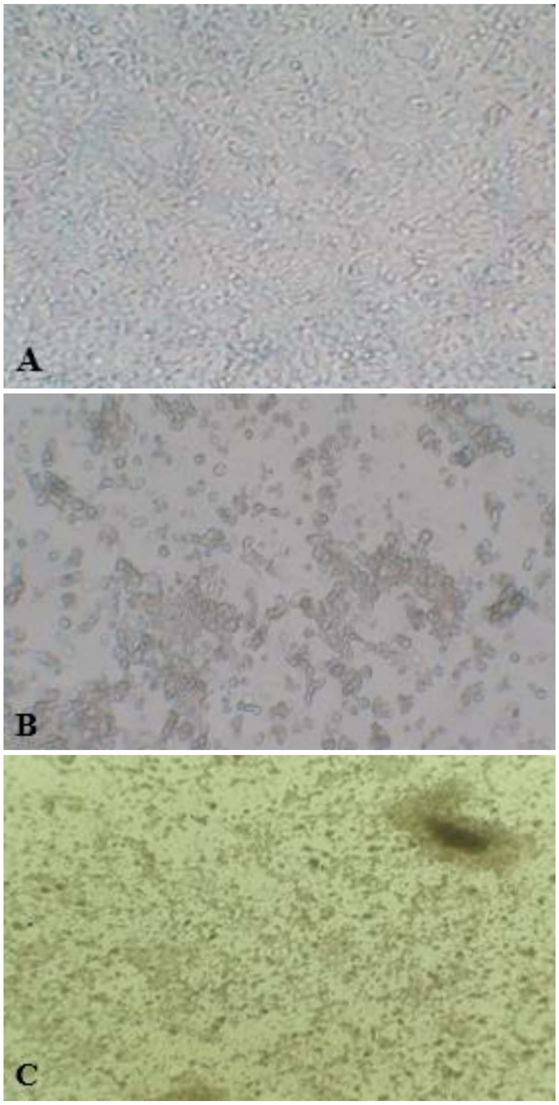
The basis of this study was to show that the involvement of viruses can be an important factor in the upper respiratory system of patients. In this study, adenovirus was studied as one of the causes of conflict in the upper respiratory tract of children.

The samples used in our study were taken in Baqiyatallah (as) Hospital from patients with ages of fewer than ten years who had symptoms such as common cold, pharyngitis, and fever. As permissive cells for adenovirus, HEK cells infected with the virus show typical CPE that resembles grape-like clusters. HEK cells were cultured in three T25 flasks grown in Dulbecco's altered Eagle medium (DMEM (1X)) enriched with 10% FBS and 1% Pen Strep (10000 Unit/ml penicillin (P-4687) + 10000 µg/ml streptomycin (S-1277) Bio-Idea made from SIGMA powder).

When the cell confluence in the flask was approximately 100%, the patient samples were inoculated by the cells in an incubator with CO2 for one hour, after which samples were washed with PBS and added to each flask containing maintenance medium (DMEM (1X) enriched with 2% FBS and 1% Pen Strep).

Flasks were incubated in an incubator at 37 °C and 5% CO2. Flasks were checked daily to observe CPE. On the third day, CPE started formation in the two flasks infected with the virus, which included rounding of cells to clustering. Almost on the seventh day, grape-like clusters, which are typical CPE for adenovirus, were visible (Figure 1).

Figure 1: The cytopathic effects in cells after inoculation. A) Control cells that had not been inoculated with the virus. B & C) Patient samples 1 and 2 in the two inoculated flasks. Cytopathic effect was evaluated daily. The result was observed associated with adenovirus infection including grape-like clusters by separating the cells from the bottom of the flask

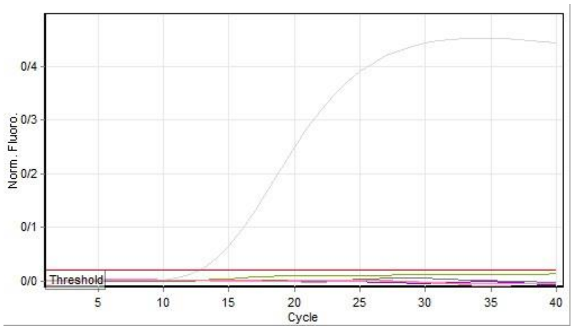


According to the figure of real-time PCR, clinical samples were positive for adenovirus in the form of double. The diagram shows that the amount of virus in sample 1 is greater than that of sample 2 (Figure 2A). Figure 2B shows real-time PCR results and related explanations.

DISCUSSION

Virus-related respiratory infections are prevalent during the year in all age clusters and all populations worldwide. Respiratory viruses can induce moderate ailments, including the common cold, or acute sickness (e.g., pneumonia), which affect both immunocompetent and immunocompromised hosts [17]. Despite the infection of both the upper and lower respiratory tract by every respiratory virus, special syndromes (e.g., croup or laryngotracheobronchitis) happen clinically by particular viruses. Both DNA and RNA viruses are reported to induce respiratory infection [18]. Researchers have described several novel viruses that have relationships with respiratory illnesses [19]. Pandemics of adenovirus respiratory infection are prevalent during winter, spring, and early summer, with protracted (a length of 1–3 years) durations [20]. Almost 80% of upper RTIs occur by viruses etiologically and can exacerbate asthma and acute otitis media [21].

Figure 2. A) Adenovirus molecular test results (real-time PCR) confirming the presence of adenovirus. In this test, a sequence-specific primer pair and a probe were used for the viral hexon sequence. B) Shows real-time PCR results and related explanations. In this test, other viruses were used as a negative control, the results of which are obvious.



No.	Colour	Name	Type	Ct
22	🟩	HSV1	Negative Control

28	⬜	Adenovirus	Positive Control	12/69
31	⬛	HSV2	Negative Control	
37	🟪	CMV	Negative Control	
40	🟥	BKV	Negative Control	

Adenoviruses are the leading respiratory pathogenic agents and account for 5-8% of all RTIs in newborns and youngsters aged two years [22]. HAdV infections have clinical similarities to those of other respiratory viruses, and it is difficult to decisively detect and swiftly diagnose the virus type, which is not achievable clinically [23]. Due to the persistency and protracted casting of adenovirus, methods of diagnosis should have sufficient sensitivity for detecting small amounts of virus in clinical samples. Several laboratory methods are available to detect adenoviruses, including nested PCR, real-time PCR, PCR, IF, and cell culture, of which molecular and cell culture techniques are sensitive enough to detect the virus [24]. The viral antigen is swiftly detected by IF but is mostly not sensitive to detect some viruses;

hence it is occasionally required to be confirmed by viral culture [25]. Molecular analyses based on polymerase chain reaction (PCR) are gaining ground for diagnosing virus-related respiratory infections and conducting epidemiologic examinations [26]. As a benchmark, viral culture was well-known to test viral respiratory pathogens. Even so, the technique suffers from slowness in general, which usually requires over 14 days to deliver results [27]. Although the number of positive results can be increased by combining these two procedures, existing reports indicate that a considerable number of samples remain negative despite suspicious viral infections both clinically and epidemiologically [28]. During the last years, a growing body of evidence has been presented on the development of molecular biology diagnostic methods for viral infections, which will undoubtedly be the benchmark approaches presently applied in ordinary laboratory assays [29]. Molecular procedures significantly contributed to the fast detection of pathogenic viruses accompanying acute respiratory infections, which allow for rapid implementation of therapeutical actions and preemptive policies to prevent disease dissemination with high transmission ability [30]. Studies in Iran, Kenya, Brazil, China, Australia, and Hong Kong showed that 5-22% of samples were affected by adenoviruses [31].

Given the importance of cell culture and real-time PCR methods in recognition of respiratory adenovirus, cell culture was confirmed by real-time PCR in this study. Their grape-like clusters identified the CPE of the adenovirus in the cell culture. From the results of real-time PCR, it is concluded that the upper respiratory tract symptoms in children of our study might have arisen by adenoviruses. Suppose a large number of patients could be studied epidemiologically on this subject and in case of obtaining statically significant results. In that case, the season of adenovirus infection frequency can be verified in the studied district to demonstrate possible differences in the season frequency of infection.

CONCLUSIONS

This study showed that simultaneous use of tests such as cell culture and PCR-based tests, including the Real-time PCR, are somewhat reliable methods for detecting adenovirus in clinical specimens.

Investigating the effect of methylprednisolone pulse on the treatment of back pain

Masoud Hatefi[1], Khalil Komlakh[2], Lida Nouri[3]

Abstract: *Background: Pain is a common problem afflicting humanity. Back pain is a musculoskeletal disorder with a high prevalence; this pain may occur to anyone at least once during their lifetime.*

Aim: the present study was performed to investigate the effect of the use of methylprednisolone pulse on the pain status of patients suffering from back pain in Ilam city.

Methods: This study is a clinical trial conducted as double-blind in 2021 in Ilam city with pretest and post-test groups plus a control group. The patients referred with vertebral disc herniation diagnosis suffering from diffuse pain in the right leg were assigned into test and control groups. A methylprednisolone 500 mg IV would be administered to the patient as pulse inside DW 500cc serum. The extent of pain was compared before and after the intervention at one, two, three, and seven days later. Placebo was applied for the control group patients. The data were analyzed by SPSS 16 as well as based on descriptive and analytical tests.

Results: According to the findings, no statistically significant difference was observed between the demographic characteristics of patients receiving methylprednisolone and patients in the control group ($p<0.05$). Also, the result showed the comparison of pain scores of patients in the two groups. According to the findings, the M (SD) pain score in the experimental group was 6.59 (0.88) before the intervention and 1.76 (0.69) in the week after the intervention, which was statistically significant ($P=0.000$). Also, the changes in the control group's score before intervention were 6.82 (0.71) and after the intervention was 6.77 (1.12) ($P>0.05$).

Conclusions: Considering the effect of methylprednisolone on mitigating the pain of patients suffering from back pain, it is suggested to use injective methylprednisolone for reducing the pain of patients suffering from back pain.

Keywords: *methylprednisolone, back pain, pain*

BACKGROUND

Pain is a common problem afflicting humanity [1]. Pain causes the development of numerous problems and constraints for the patient including reduction of quality of life, psychological health, life expectancy, daily activities, spiritual health plus related factors [2-5], as well as the development of depression, disability, and stress [6,7]. Back pain is a musculoskeletal disorder with a high prevalence; this pain may occur to anyone at least once during their lifetime [8]. Today, with changes that have occurred in the lifestyle of people, different groups may experience this pain, and this disease may happen in response to ergonomic-mechanical, as well as individual and social factors [9]. Back pain is a common cause of visits and medical interventions. Chronic back pain has considerable effects on functional status, constraining occupational activity, and certain socioeconomic consequences [10,11]. Among skeletal disorders, the damage related to back pain claims the largest share and in addition to healthcare aspects, it has also attracted the public attention economically [12]. The causes of this disease are numerous and its precise identification is sometimes difficult. Back pain is considered an important health problem that is common in all countries, especially industrial ones. Musculoskeletal disorders are typically

associated with symptoms such as pain as well as permanent disorders in muscles, joints, nerves, and tendons. The effects of back pain may go beyond pain, which can be very serious and profound, causing incurrence of indirect costs, diminished capacity of individual ability, and increased risk of suffering from other medical conditions [13-15].

In pain etiology, various factors are involved, and one of the common features in all of them is neck movements; as these movements increase, so does the pain in that region [16]. Radiculopathy refers to nerve root disorders that may develop in response to structural injuries such as disk, tumor, trauma, vascular disorders, or infection such as viruses [17]. The radicular back pain is a kind of neuralgia that develops following sensory root stimulation or the dorsal root ganglion of the spinal nerve. Radicular back pains occur because of the generation of abnormal impulses in the dorsal root ganglion and its transfer through the peripheral nerve axon [18,19].

Different studies have been performed for the treatment of back pain and various therapeutic protocols have been criticized and examined. These methods include nonpharmacological methods such as educational intervention [20], exercise interventions [21], spiritual care [21], distraction [22], as well as pharmacotherapy [23]. There are different drugs for mitigating the pain in patients suffering from radicular pain including methylprednisolone. Prescription of this drug can help treat spinal nerve injury given its anti-inflammatory properties, immunosuppression, and improving neurological recovery [24].

OBJECTIVES

Identification of pain mitigation methods and especially attempts in choosing the best pain alleviation method in neurosurgery patients is one of the most important duties of neurosurgeons. This can be effectuated only through clinical research and performing interventional studies in this regard. Accordingly, the present study was performed to investigate the effect of the use of methylprednisolone pulse on the pain status of patients suffering from back pain in Ilam city.

METHODS

Study Design

This study is a clinical trial conducted as double-blind in 2021 in Ilam city with pretest and post-test groups plus a control group. The patients referred with vertebral disc herniation diagnosis suffering from diffuse pain in the right leg were assigned into test and control groups. A methylprednisolone 500 mg IV would be administered to the patient as pulse inside DW 500cc serum. The extent of pain was compared before and after the intervention at one, two, three, and seven days later. Placebo was applied for the control group patients.

Study Population

The statistical population in this study consisted of patients referring to hospitals, clinics, and practice offices of physicians in Ilam where the radicular pain. The sample size consisted of 94 patients; after the intervention, 12 of them were excluded, and eventually, the data were analyzed by 42 patients in the experimental group and 40 patients in the control group.

Inclusion and Exclusion Criteria

Inclusion Criteria

Informed consent for participation in the study, aged older than 20 years, at least three months past the disease, definite diagnosis of the disease by a neurosurgeon, and patients suffering from diffuse pain in the right leg were the inclusion criteria.

Exclusion Criteria

Desire to leave the study at any time, history of consuming medications other than the drugs of the intervention, history of any other disease affecting pain, and requiring surgery for radicular pain treatment constituted the exclusion criteria. Furthermore, patients with underlying problems, spondylolisthesis, spinal tumors, and congenital lesions were also excluded.

Ethical Approval

Receiving ethics code in the research with the code IR.MEDILAM.REC.1400.118, voluntary participation or lack of participation in the study, freeness of all visits, medications, and costs related to the interventions, confidentiality of patient information, explaining the objectives of pharmacological intervention with an understandable language for patients.

Study Tools

Demographic characteristics form and pain scale were used. VAS pain scale was applied to determine the severity of patients' pain. This scale is a 10 cm graduated ruler, which was used here for scoring the most severe pain and zero score according to the patient's report. In this instrument, acquiring a score 1-3 represents mild pain, a score 4-7 moderate pain, and a score 8-10 severe pain (25).

Statistical Analysis

The data were analyzed by SPSS 16 as well as based on descriptive and analytical tests.

RESULTS

According to the findings of Table 1, no statistically significant difference was observed between the demographic characteristics of patients receiving methylprednisolone and patients in the control group (p<0.05).

Table 2 showed the comparison of pain scores of patients in the two groups. According to the findings, the M (SD) pain score in the experimental group was 6.59 (0.88) before the intervention and 1.76 (0.69) in the week after the intervention, which was statistically significant (P=0.000). Also, the changes in the control group's score before intervention were 6.82 (0.71) and after the intervention was 6.77 (1.12) (P>0.05).

Table 1: Comparison of demographic characteristics of patients under study

Pain		Experimental Group	Control Group	P
		N (%)	N (%)	
Gender	Male	23 (54.8)	25 (62.5)	0.48
	Female	19 (45.2)	15 (37.5)	
Marital status	Married	29 (69)	28 (70)	0.92
	Single	13 (31)	12 (30)	
Economic situation	Weak	19 (45.2)	10 (25)	0.11
	Medium	18 (42.9)	24 (60)	
	Excellent	5 (11.9)	6 (15)	
Age, M (SD)		51.87 (18.46)	51.52 (9.40)	0.91

Table 2: Comparison of demographic characteristics of patients under study

Pain	Experimental Group	Control Group	P, F
	M (SD)	M (SD)	
Pain pre intervention	6.59(0.88)	6.82(0.71)	P=0.2, F=2.38
pain after 1 days	4.88(1.08)	6.72(0.59)	P=0.000, F=9.34
pain after 2 days	3.83(0.62)	6.45(0.95)	P=0.000, F=11.43
pain after 3 days	2.50(0.63)	6.35(1.23)	P=0.000, F=14.04
pain after 7 days	1.76(0.69)	6.77(1.12)	P=0.000, F=4.66

DISCUSSIONS

This study was conducted to explore the effect of methylprednisolone on pain mitigation among patients suffering from radicular back pain. The group of patients suffering from back pain claims a considerable percentage; in the meta-analysis by Azizpour et al., it was found that the prevalence of back pain in 20 papers with a total sample size of 5670 subjects was 51%, mostly afflicting 15-50-year-old age group [26] as the largest prevalence. As such, this group of patients requires special attention.

In this study, the usage of methylprednisolone drug could lead to a reduction of patient back pain. In a retrospective study by Dobohue et al. to compare methylprednisolone and dexamethasone drugs on pain mitigation, it was found that although both drugs could reduce the patient's pain, there was no significant difference between the two drugs against the patient pain mitigation. Further, methylprednisolone at two months following the intervention had caused 65% pain reduction for patients, which was 75% for dexamethasone [27]. In the study by Li et al., to explore the effect of methylprednisolone on neuropathic pain, they found that methylprednisolone could lead to improvement of quality of life and mitigation of pain. In that study, the extent of pain reduction was reported as about 50% or more [28].

The findings of other studies have also concurred with the present study results. In the meta-analysis by Liu et al. analyzing six clinical trial studies, 350 patients met the inclusion criteria. The results of this meta-analysis showed that usage of methylprednisolone at 6 and 24 h post-injection could result in pain alleviation for patients. Further, injection of this drug contributed to reduced nausea and vomiting for the researched patients [29]. Also, in the study by Lunn et al. on patients with total knee arthroplasty, again methylprednisolone had led to a reduction of pain and fatigue as well as an improvement in sleep quality [30]. The results of the mentioned studies [29,30] have been in line with the findings of the present study regarding the effect of methylprednisolone on pain alleviation in patients.

CONCLUSIONS

Considering the effect of methylprednisolone on mitigating the pain of patients suffering from back pain, it is suggested to use injective methylprednisolone for reducing the pain of patients suffering from back pain.

Laparoscopic sleeve gastrectomy and esophageal motility

Andrada L. Popescu[1,2], Raluca S. Costache[1,2], Sandica Bucurica[1,2], Mihaita Patrasescu[1,2], Vasile D. Balaban[1,2], Florin A. Savulescu[1,3], Mariana Jinga[1,2], Florentina Ionita-Radu[1,3], Carmen Fierbinteanu-Braticevici[2,4]

Abstract: *Laparoscopic sleeve gastrectomy (LSG) is becoming popular between the bariatric procedures. There are few studies available in the literature about LSG impact on esophageal motility, with debatable results. Technically, it modifies the anatomy of the esophago-gastric junction; it can damage the phreno-esophageal ligament and decrease the lower esophageal sphincter pressure that will predispose to reflux. Gastroesophageal reflux disease (GERD) is already common in obese patients due to frequent hiatal hernia, high intraabdominal pressure, increased transient lower esophageal sphincter relaxations (TLESR), altered esophageal motility and poor esophageal clearance. LSG can worsen gastroesophageal reflux disease, but also the weight loss achieved after it and the decrease of acid production in the small gastric pouch will probably reduce the GERD symptoms. Dysphagia and odynophagia were reported after sleeve gastrectomy, but usually associated with anatomical narrowing of the gastric sleeve, caused by esophageal dismotility or secondary to diabetes mellitus, low tiamine level, the use of opioids and non-steroidal anti-inflammatory drugs, even hypothyroidism. In addition to upper GI tract endoscopy, high-resolution esophageal manometry (HRM) should be required for all patients planning to undergo a LSG, and in the follow-up period according to the contractility pattern.*

Keywords: *obese, sleeve gastrectomy, esophageal motility, esophageal clearance, reflux*

INTRODUCTION

According to World Health Organization (WHO), overweight and obesity are defined as abnormal or excessive fat accumulation that presents a risk to health. If the Body Mass Index (BMI weight in kilograms divided by the height in square meters) is between 25-30 kg/m^2 a person is overweight, and if BMI > 30 kg/m^2 obese [1]. Unfortunately due to behavioral and nutritional changes more than 20% of the worldwide population is overweight and 10% obese, and in the next 20 years the estimation is that 2.16 billion people will be overweight and 1.12 billion obese [2].

Morbid obesity, defined by BMI greater than 40 kg/m^2 or between 35 and 40 kg/m^2 with any obesity-associated conditions such as diabetes, high blood pressure, cardiovascular disease, stroke, sleep apnea, osteoarthritis, is a serious invalidating health condition that can interfere with basic physical functions such as breathing or walking [3].

The first step to obtain weight loss is through behavioral and lifestyle changes, with low-calorie diet and exercise, but usually previous attempts of weight loss are followed by rapid weight regain. Many obese associate to diet and exercise pharmacological drug therapy, achieving maximum 10% weight loss [5]. Unfortunately, a lot of patients fail to achieve long-term weight loss through these methods, so they are good candidates for surgical treatment.

Bariatric surgery cause weight loss by restricting the amount

of food in the stomach, or by a combination of gastric restriction and malabsorption[6]. The bariatric surgical procedures can be purely restrictive, such as laparoscopic adjustable gastric band (LAGB) or laparoscopic sleeve gastrectomy (LSG), or malabsorptive-restrictive: Roux-en-Y gastric bypass (RYGB) and biliopancreatic diversion (BPD)[3, 6]. All the bariatric surgical procedures may have local complications (stenosis at anastomotic sites, stomal ulcers, band erosion, fistulae) but they can be managed with proper follow-up and close monitoring.

Table 1: The known risk factors [4] for morbid obesity are:

1. Genetic factors (familyhistory of obesity)
2. Dietaryhabitsandsedentary lifestyle, **q**uittingsmoking, microbiom
3. Stressandanxiety (highlevel of cortisol, high-calorie food)
4. Sleepdisorders
5. Female (post pregnancyweightgain or menopause)
6. Aging (slowingdown metabolism)
7. Somemedications (antidepressants, steroidsand beta-blockers)
8. Cushing'ssyndrome, Prader-Willi syndrome

The laparoscopic adjustable gastric band (LAGB) involves an inflatable band that is placed around the upper portion of the stomach, creating a small gastric pouch and reducing the amount of food. Is a reversible procedure, with shorter hospital stay and low mortality rate, but the band can slip or create erosion into the stomach, requires a foreign device to remain in the body and strict adherence to the postoperative diet and follow-up visits. The weight loss achieved is slower than the other bariatric procedures, with low risk of vitamin/mineral deficiencies, but a high rate of re-operation [6].

The Roux-en-Y gastric bypass was considered the “gold standard” of weight loss surgery, restricting the amount of food consumed and modifying hormonal level of ghrelin, decreasing appetite an enhance satiety. But is technically more complex than LAGB or laparoscopic sleeve gastrectomy (LSG), has longer hospital stay with possible long-term vitamin/mineral deficiencies (vitamin B12, calcium, folate, iron). Nowadays, remains an effective method to alleviate symptoms of GERD and many bariatric procedures are finally converted to Roux-en-Y bypass [6].

Laparoscopic sleeve gastrectomy (LSG) consist of a vertical division on the larger curvature of the stomach, removing a large portion of the body and all of the fundus, the effect being both restrictive and endocrinologic – reducing ghrelin. LSG is very popular among the bariatric procedures, it induces rapid and sustainable weight loss of > 50% for 3-5 years, has relatively short hospital stay (48h), but is a non-reversable procedure with potential long-term vitamin deficiencies [6]. Also, transforming the stomach into a cylindrical structure and altering the anatomy of the esophago-gastric junction will probably influence the lower esophageal sphincter pressure and esophageal motility.

OBESITY AND ESOPHAGEAL HEALTH

Gastroesophageal reflux disease (GERD) is common in obese patients, and they can be even more sensitive to the presence of acid in the esophagus than a normal weight person. Also, hiatal hernia, a risk factor predisposing to GERD is more prevalent among the obese [7]. Obesity may trigger vagal abnormalities and a higher level of bile and pancreatic enzymes, worsening the effect on esophageal mucosa [8].

According to a meta-analysis published by Halmpel H. et al. in 2005 [9], obesity may increase the risk of GERD symptoms by 50%, and also cause a 2-fold increase in esophageal adenocarcinoma [9]. The pathophysiological mechanisms of increased GERD in obese are: high intraabdominal pressure, frequent hiatal hernia, increased transient lower esophageal sphincter relaxations (TLESR), lower esophageal sphincter (LES) pressure, altered esophageal motility with poor esophageal clearance [10, 11].

The esophageal transit time in obese has been in the researchers preoccupation from1985, when Mercer CD et. al [11] measured it by radionuclide scintigraphy using a swallowed technetium sulfur colloid bolus. The data obtained were compared from obese patients with GERD to normal weight with and without GERD. The esophageal transit time was significantly prolonged in the obese group compared with both lean groups (p less than 0.001). Also performing conventional esophageal manometry theyconfirmed that in obese patients gastroesophageal pressure gradient is elevated [12].

Furthermore, in a study published in Obese Surgery in 1999, Jaffin BW et al. revealed a high prevalence of asymptomatic esophageal motility disorders among morbidly obese patients. During a 3-year period, they evaluated manometric and completed a questionnaire of symptoms, medications, demographic data, other medical conditions associated, 111 obese patients for bariatric surgery. Abnormal manometric findings were observed in 61% patients: 14% hypertensive contractions of the esophageal body, 7% diffuse esophageal spasm (DES), 1% achalasia, 25% hypotensive lower esophageal sphincter defined by LES pressure < 10 mm Hg, and 14% were nonspecific esophageal motility disorders [13].

Similar results have been obtained by Koppman's team [14], after performing esophageal manometric evaluation in 116 obese patients selected for laparoscopic gastric banding in 2003. 41% of the patients had abnormal manometric findings: 23% nonspecific esophageal motility disorders, 11% hypertensive contractions, 1% diffuse esophageal spasm, 1% achalasia, 3% isolated hypertensive LES pressure (>35 mmHg), 3% isolated hypotensive LES pressure (<12 mmHg). Only one patient with abnormal esophageal motility reported noncardiac chest pain [14].

LAPAROSCOPIC SLEEVE GASTRECTOMY AND ESOPHAGEAL MOTILITY

In a review of the impact of laparoscopic sleeve gastrectomy on gastrointestinal motility, published in 2018 by Eleni Sioka et al. [15], after a search of the medical literature with two independent reviewers, they selected only 9 eligible studies that focused on esophageal motility [16]. The esophageal motility data were debatable, with differences regarding the follow-up timing (from 6 weeks to median 13 months), the study design, the surgical technique, the bougie size, and the distance from pylorus. To clarify this subject we need more data from future prospective studies on larger cohorts.

Del Genio G et al. [17] studied the impact of LSG on esophageal physiology, performing high-resolution impedance manometry (HRiM) combined 24-h pH and multichannel intraluminal impedance (MII-pH) before and after the procedure, in 25 patiens. After a median follow-up of 13 months, HRiM showed increased ineffective peristalsis and incomplete bolus transit, but normal LES function.

In a retrospective analysis of 53 cases of HRiM performed after LSG, Mion F. et al. [18] found in 77% of patients an increased intragastric pressure (IIGP), even if they were asymptomatic with no specific manometric or impedance changes, and this could be assimilated as a manometric marker of LSG.

An interesting study of Petersen WV et al. [19] published in 2012, proved that LSG increased lower esophageal pressure independent of weight loss achieved after the procedure, thus protecting obese patients from gastroesophageal reflux.

Dysphagia was reported after laparoscopic sleeve gastrectomy, but usually associated with narrowing of the gastric sleeve which means inability to pass a 9.6 mm gastroscope due to stenosis or a sharp angulation [19]. In a study published by A. Nath et al. in september 2016, from 352 patients included, 22.7 % had dysphagia, 9.3% narrow sleeve, 7.1 % sharp angulation, 2.3% stenosis, and they responded well to ballon dilatation (1-3 sessions). Other medical conditions were associated with post-operative dysphagia: esophageal reflux, diabetes, low tiamine level, opioids and non-steroidal anti-inflammatory drugs or hypothyroidism, so dysphagia is not a specific esophageal motility disorder sign [20].

PRACTICAL CONSIDERATIONS

We performed a prospective study in Carol Davila University Central Emergency Military Hospital to determine the manometric pattern of obese patients, the prevalence of esophageal motility disorders prior and after gastric sleeve and the upper GI complications post sleeve.

The aim was to do high-resolution esophageal manometry (HRM) to all obese patients proposed for LSG, before and 6 to 12 months after the procedure, plus upper GI tract endoscopy and GERD questionnaire (GERD-HRLQ). Starting from January 2017, we included in the study 61 morbid obese patients evaluated both endoscopically and manometric. The exclusion criteria were: previous gastric surgery, another bariatric procedure surgical or endoscopically, the use of medications that could affect esophageal contractility or lower esophageal sphincter pressure (prokinetics, calcium-blockers, nitrates). Half of the patients are now in the post-operative evaluation period, because of surgical intervention timing, and the final results will be later published.

Esophageal manometry was performed with a 36-channel High-Resolution Solid State Catheter from Sierra-Given, after 6 h of fasting and previous upper GI tract endoscopy evaluation. The manometric data were obtained through 10 single test swallows of 5 ml of water. The HRM results were then analyzed according to the Chicago Classification v3.0 of esophageal motility disorders, using the ManoView ESO software program (component of the ManoScan system), providing visual images and quantitative physiological parameters.

The principal manometric variables analyzed [21] were summarized in the Table 2.

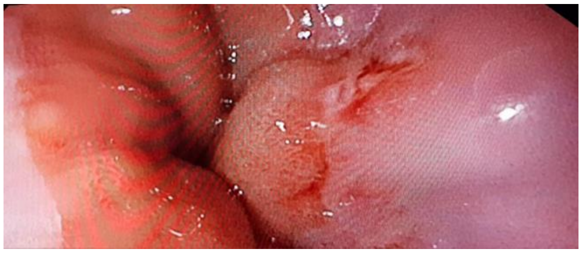
Diffuse esophageal spasm (DES) causes chest pain and sometimes mixed dysphagia for both liquids and solids. The substernal chest pain may waken the patient from sleep or is associated with exercise and often confused with angina pectoris. Hot or cold liquids may aggravate the pain. From the current data available, it is possible that in time this disorder to evolve into achalasia with impaired esophageal peristalsis and lack of lower esophageal sphincter relaxation during swallowing. Usually barium swallow may show poor progression of bolus plus simultaneous contractions [22]. Fragmented peristalsis and ineffective motility are minor esophageal motility disorders according to Chicago Classification v3.0 which can be seen also in normal person.

A particular manometric pattern was found during our study, in a 42-year-old female with morbid obesity BMI = 44.81 kg/m^2 (W= 122 kg, H= 165 cm), obstructive sleep apnea and minor GERD symptoms prior to the surgical intervention. The upper gastrointestinal endoscopy revealed erosive esophagitis grade A, duodenitis with Helicobacter pylori infection both treated preoperative.

Table 2: Principal manometric variables analyzed

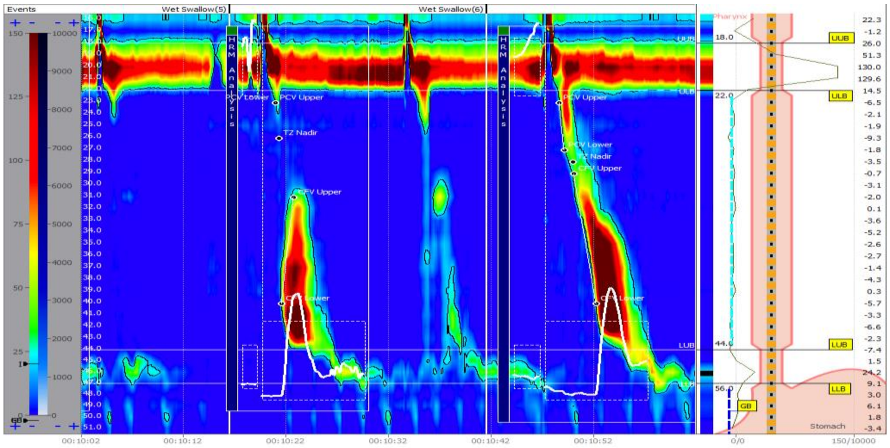
Lower esophageal sphincter(LES) resting pressure	Normal 13-43 mmHg
Deglutitive LES relaxation = Integrated Relaxation Pressure (IRP)	For Sierra-Given solid probe the normal value < 15 mmHg
Esophageal peristalsis = Distal Contractile Integral(DCI)	Normal 500 – 5000 mmHg-cm-sec; > 5000 Hypertensive > 50% contractions weak (DCI < 500) or failed (DCI < 100) = IEM Ineffective motility
Duration of contraction waves in seconds= Distal Latency (DL)	Normal value > 4.5 sec, if 2 contractions are premature < 4.5 sec the diagnose is Diffuse esophageal spasm(DES)
Peristaltic break > 5 cm	More than 50% of swallows = Fragmented peristalsis(FP)

Figure 1: The upper GI tract endoscopy image preoperative – erosive esophagitis grade A Los Angeles Classification



On the preoperative high-resolution esophageal manometry (HRM) she had normal lower esophageal sphincter (LES) basal pressure, LES length = 3 cm, normal deglutitive LES relaxation, with IRP median value of 6.6 mmHg, good esophageal contractility (DCI median= 956.1 mmHg-cm-sec and DCI maximum=1305.7 mmHg-cm-sec) but > 20% premature contraction (distal latency value < 4.5 seconds), aspect of diffuse esophageal spasm according to Chicago Classification v3.0.

Figure 2: Wet 5-ml test swallows recorded with HRM preoperatory – shorten distal latency



Considering the high cardio-vascular risk in a young patient, severe obstructive sleep apnea, the failure of diet and exercise and the need for sustainable weight loss, we didn't contraindicated the laparoscopic sleeve gastrectomy, but we've decided to closely follow the patient.

The laparoscopic surgical intervention went well, with good recovery after the procedure, good tolerance of food intake implementing the diet and exercise protocol. One year after LSG, the patient lost 40 kg, achieved a BMI of 30 kg/m^2 and had 82 kg weight. Clinically, now she had mild dysphagia, early satiety and fullness (that can be related to the low volume of the stomach), and less reflux symptoms compared to baseline.

The result of upper gastrointestinal endoscopy was encouraging: no evidence of erosive esophagitis, a normal gastric scar on the posterior wall of the stomach after LSG, as you can see in Figure 3.

Postoperative data from high-resolution esophageal manometry (HRM) examination revealed normal lower esophageal sphincter basal pressure (mean 20.2 mmHg, min -0.8 mmHg) with normal deglutitive relaxation of LES > 60%, mean IRP value 2.2 mmHg, the same LES length of 3 cm, but more than 50% of the esophageal contractions ineffective, with a DCI < 500 mmHg-cm-sec and normal distal latency, diagnosis of IEM ineffective motility according to Chicago Classification. Increased intragastric pressure (IIGP) after 5-ml water swallows was observed in 30% of the ten swallows examined.

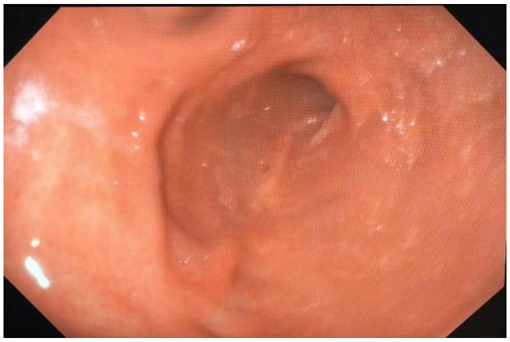


Figure 3: The longitudinal scar on the posterior wall of the stomach after LSG

Figure 4: Wet 5-ml test swallows recorded with HRM postoperatory – ineffective motility

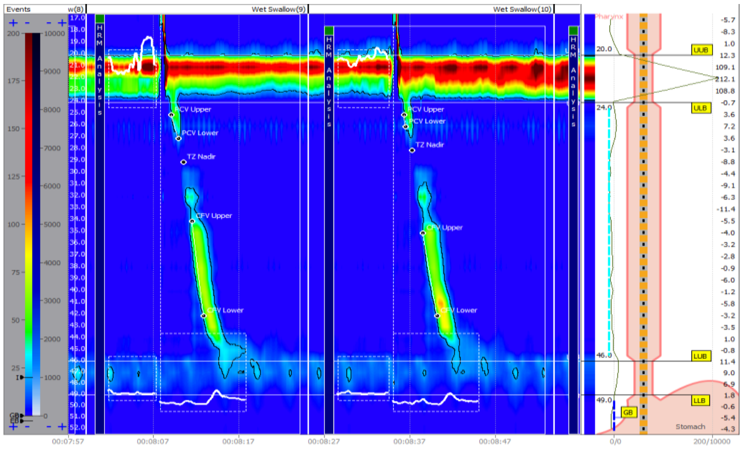

Table 3: The manometric data of LES 1-year after the LSG, no criteria of SED or achalasia as expected

Pressure meas. method	eSleeve	Normal
Basal (respiratory min.)(mmHg)	– 0.8	4.8-32.0
Basal (respiratory mean)(mmHg)	20.2	13-43
Residual IRP (mean)(mmHg)	2.4	<15.0
Residual (highest)(mmHg)	17.9	
Percent relaxation(%)	91	

Table 4: The manometric data of distal esophageal contractility 1-year after LSG (low mean value of DCI = hipocontractility)

High Resolution Parameters		Normal
Distal contractile integral(mean)(mmHg-cm-s)	444.4	500-5000
Distal contractile integral(highest)(mmHg-cm-s)	666.7	
Contractile front velocity(cm/s)	2.9	<9
Intrabolus pressure (@LESR)(mmHg)	– 0.5	<8.4
Intrabolus pressure (avg max)(mmHg)	3.4	<17

Table 5: Detail of all 10 wet test swallows recorded 1-year post LSG
(3 failed with DCI < 100 mmHg-cm-sec, 4 weak DCI < 500 mmHg-cm-sec).

	N	Med	1	2	3	4	5	6	7	8	9	10
DCI distal contractil integral (mmHg-cm-sec)	500-5000	444.4	666.7	N/A	422	182.6	N/A	375.7	557	515.2	391.3	N/A

Our patient experienced dysphagia after laparoscopic sleeve gastrectomy, but the GERD symptoms ameliorate. The HRM showed ineffective esophageal motility (IEM) and not achalasia as expected [16]. IEM is considered a minor motility disorder which can be seen also in asymptomatic patients according to Chicago Classification v3.0, but it was also cited by Del Genio G et al. after LSG [17]. We found 30% increased intragastric pressure (IIGP) after water swallows, corresponding to Mion F et al. data [18]. Further manometric follow-up is needed in this patient to see the contractility evolution pattern.

CONCLUSIONS

High resolution manometry (HRM) was already indicated for the preoperative assessment of peristaltic function in patients who needed antireflux surgery, but we consider that it is necessary to extend the HRM recommendation to bariatric surgery for better management of complications.

Studying the manometric changes in obese patients prior to laparoscopic sleeve gastrectomy is important, because it helps to select those patients who could develop postoperative esophageal motor complications and refractory reflux. In addition to upper GI tract endoscopy, high resolution esophageal manometry (HRM) should be required for all patients planning to undergo a LSG.

A proposed alternative to pharmacological treatment to relieve post laparoscopic sleeve gastrectomy GI symptoms is usually the Roux-en-Y gastric bypass, which is considered an effective method to alleviate symptoms of GERD, but it will not resolve the poor esophageal contractility. In conclusion, conversion to gastric bypass is not an universal method for managing GI complications, especially esophageal dysmotility after LSG, so we need to choose wisely the patient eligible for sleeve.

REVIEW

Leadership skills in surgeons: a review of the literature

Alexandra Sopu[1], Juergen Apel[1]

Abstract: *Clinicians, professors of medicine in general, students, and professionals from the health sciences tend to focus their efforts on technical training related to their discipline in practice as well as activities that produce some benefit direct or personal satisfaction. It is unusual to devote time and effort to training in areas such as teaching or expand their skills in sociological and organizational aspects. Would you like to take a course on strategic planning if not a director or officer of the hospital? Manage time in your schedule for a workshop on communication and conflict management? Have room in your schedule for educational activities on leadership, organizational change, and diffusion of innovations, science or science complexity of implementation? Generally, doctors and teachers do not spend much time on these activities (at least voluntarily) because we feel that what we have learned from these topics on personal experience is enough [1].*

Effective teamwork, not only in the operating room but also throughout the perioperative route is considered an important and critical component of the safety and effectiveness of surgical care and leads to good results and quick recovery of surgical patients. Therefore, considerable efforts have been made to understand how teams work within the route of surgical care and to improve teamwork [2].

The simple act of bringing together some experts does not guarantee that turned out an expert team. Given the evidence suggests that teamwork in the operating room sometimes is far from harmonious and effective, the importance of training the surgical team to work effectively is receiving international acceptance as a key strategy to maximize safety in surgery.

This systematic literature review aims to present a review of literature that focuses on the importance and role of leadership skills in the surgeon and how these skills can play a significant role in increasing the quality of care and patients' safety in operating room (OR) settings.

Keywords: *leadership, surgeons, operating room, qualities, leader, surgical team, conflict*

INTRODUCTION

Clinicians, professors of medicine in general, students, and professionals from the health sciences tend to focus their efforts on technical training related to their discipline in practice as well as activities that produce some benefit direct or personal satisfaction. It is unusual to devote time and effort to training in areas such as teaching or expand their skills in sociological and organizational aspects. Would you like to take a course on strategic planning if not a director or officer of the hospital? Manage time in your schedule for a workshop on communication and conflict management? Have room in your schedule for educational activities on leadership, organizational change, and diffusion of innovations, science or science complexity of implementation? Generally, doctors and teachers do not spend much time on these activities (at least voluntarily) because we feel that what we have learned from these topics on personal experience is enough [1].

The way to see the errors and patient safety has changed radically over the last 15 years. Effective teamwork, not only in the operating room but also throughout the perioperative route is considered an important and critical component of the safety and effectiveness of surgical care and leads to good results and quick recovery of surgical patients. Therefore, considerable efforts have been made to understand how teams work within the route of surgical care and to improve teamwork [2].

During the past 15 years, the conceptualization of security in surgery has changed substantially. There is a growing awareness that the skills required to consistently achieve security in surgery go far beyond the knowledge and technical skills of the surgeon [3]. Teamwork, defined in terms of "a set of behaviors, actions, cognitions, and attitudes that facilitate the work to be done" [4], is increasingly seen as an essential component of safe surgery. Work crews are essential when "errors can result in serious consequences; when the complexity of the activity exceeds the capacity of one person; when the working environment is ill-defined or ambiguous or stressful; when you need to make many decisions quickly, and when the lives of others depend on the collective view of the members'. The importance of teamwork to the safety and efficiency of operations has been recognized for some time and, therefore, is an integral part of the education, training, and evaluation of workers in many industries. It seems that, finally, the health community begins to embrace the concept of "work teams are a source of security" [5].

The simple act of bringing together some experts does not guarantee that turned out an expert team. Given the evidence suggests that teamwork in the operating room sometimes is far from harmonious and effective, the importance of training the surgical team to work effectively is receiving international acceptance as a key strategy to maximize safety in surgery. The development of training interventions to provide surgical team knowledge, skills, and attitudes that serve as a foundation for effective performance has become a dominant theme in the literature of surgery, anesthesia, and nursing.

OBJECTIVE

This systematic literature review aims to present a review of literature that focuses on the importance and role of leadership skills in the surgeon and how these skills can play a significant role in increasing the quality of care and patients' safety in operating room (OR) settings.

METHODS

A systematic review of the available literature was performed on leadership skills in the operating room. The search was made on the PubMed, JSTOR, and Cochrane library databases on June 10th, 2020 using the following formula: (Leadership skills AND Surgeons AND Operating Room). First, the articles were screened by title and abstract. The following inclusion criteria for relevant articles were used during the initial screening of titles and abstracts: must focus on leadership skills of surgeons, must focus on models of leadership for surgeons, and must focus on skills required by surgeons to be good leaders for the OR team. Other exclusion criteria were: studies published before 2010, studies other than the English language, studies conducted in under-developed countries, studies focusing on non-technical skills other than leadership skills.

In the second step, the full texts of the selected articles were screened, with further exclusions according to the previously described criteria. Moreover, articles not reporting clinical results were excluded. Relevant data were then extracted and collected in a single database with a consensus of the two observers to be analyzed for the present manuscript.

Table 1 provides the list of articles that are included in the review.

Table 1: List of articles included in the review.

RESULTS

Importance of Leadership and Teamworking for Surgeons

From the technological point of view, surgery is highly complex and is a practice that faces a constantly changing scenario. The surgeon works in the Department of Surgery, often in a specialized unit, and participates with interdisciplinary teams, and develops their daily clinical practice with other specialists and technicians working in different settings (such as operating room, ward) [6]. The primary objective of a surgeon is to provide the best patient care, with greater safety. When required today in most prestigious forums, safe surgery for the patient, it must be remembered that the complications that arise during treatment (about 45% in surgical patients) are rarely the result of the failure of a single individual, but in over 80% of cases they are related to poor planning of patient care systems, or with failures in teamwork [7].

A significant number of studies draw attention to the importance of effective teamwork, which by nature must be interdisciplinary, to get quality treatment over the surgical patient stays. Among them are two: the one entitled “To Err is Human: Building a Safer Health System” [8] published by the Institute of Medicine in 2000, in which the high percentage of errors detected was evaluated in the Health System of the USA and the well-known Kennedy Report in May, which analyzed the very high mortality of pediatric cardiovascular surgery service in Bristol, UK. As a result of the Surgery Quality Improvement Project with which has reduced mortality by a third and two-fifths in morbidity in all the services of surgery [9]. They participated in June. The overall analysis has led to a clear conclusion: the causes of human errors and their adverse consequences for the patient are deficiencies related to teamwork, as well as the communication between its members.

While the topical figure of an individualist and arrogant surgeon, and even violent with his surgical environment, has already been exceeded, it is not uncommon that surgeons think they work together, when in fact, most do in the group [10]. Team working requires leadership essentially, to ensure that decisions making is done by consensus, analyze the reasons for the disagreements and try to fix them, ensure that the objectives are understood and accepted by the team, encourage all members to contribute their ideas, require the operation of the equipment is periodically reviewed [11]. It can only be made possible by the work of each of its members to appreciate, and finally, that leadership is shared, as necessary. Teamwork is not easy, but with good leadership and proper training of its members in cognitive abilities, and personal relationships, it can be achieved.

The results of recent research, advise that surgical services training programs to develop teamwork in specific tasks (operating room, emergency department, hospital ward), as has already been done, and successfully in other high-risk professions, such as aviation, by applying the methodology called crew resource management (CRM). The key elements of this methodology that can be applied to the work of the surgeons are: the "briefing" (a previous discussion of the action plan), the question between senior member and juniors team of decisions, and take "de-briefing" sessions (understood as the discussion of what happened afterward). Compliance with these requirements can only be achieved in an atmosphere of work and communication between members of a team in which everyone is always willing to learn [12].

The "Non-technical skills for surgeons' project, designed by the University of Aberdeen, has identified several cognitive skills and personal relationships, which must be the essential complement to the expertise of the surgeon, to keep the OR, high levels of quality and safety [13]. These skills include the surgeon's ability to exercise leadership, the state of permanent alert, the ability to take the right decision at all times, and the ability to stimulate communication and teamwork. It is currently available instruments to assess, on stage at the theatre, the teamwork, and skills that are not just technical.

Several studies have shown a relationship between teamwork (surgeons, anesthetists, and instrumentalists) [14], the "performance" and safety in the operating room. It is estimated that up to 1/3 of the duration of the activity in an operating room, communication failures occur in the team. 33% of these failures originate delays, workarounds an unsolved problem ("workaround"), increased environmental stress, unnecessary expense, and disturbance to the patient. A recent study assessed for the first time, the impact that a training course in non-technical skills (CRM methodology) had on the results of two types of surgery, showing that the improvement observed in the teamwork produced the best technical results. These data confirm, albeit in a different field, the results of the multicenter project MedTeams [15], in the US, where the application of CRM in the emergency services model was evaluated and found to a reduction in clinical errors (30.9 to 4.4%) and improved teamwork and attitudes of its members [16]. This is the clearest example of how improved teamwork can avoid complications. It is possible that system-based training, as well as patient simulators that allow the practice of specific behaviors, can avoid the need for real instructors.

However, since efficient teamwork does not arise spontaneously, should be encouraged as soon as possible the development of new hospital culture, for the hospital administration and the Department of Surgery must provide the training tools to help its implementation. But above all, it is essential to have well-trained surgical leaders, able to motivate and change, for the good behavior of team members, with the ultimate goal, to always be the best possible result for the patient. It would be desirable that scientific societies and the NHS itself develop programs similar to the Royal College of Surgeons of England, aimed at the specific training of leaders, and their corresponding surgical equipment, improving, no doubt, patient safety [17].

Leadership in Surgeons

Leadership is one of the most important qualities for a successful surgeon. Surgical outcomes depend critically on a surgical team rather than on an individual; therefore, the role of surgeons is essential for optimal management of patients in a surgical service [18]. There are different kinds of leadership: one who asks the group to follow him, the group encouraged to follow you, or those who are forced to follow. It is important to remember that the most effective leader is using different styles at different times. One should be aware of the strengths and weaknesses in him/her as a leader and recognize what kind of leadership is most often used, as must implement leadership strategies in line with the situation [19].

Several points should be present in every surgeon in assuming the leadership role within a surgical team and in OR [20]:

- One must learn the art of conflict resolution: it is important to remember that there is a conflict over a point of view and always more of a perception of truth. The surgeon should try to understand each different point and perspective, but it has not always solved them, has to determine the ideal to maintain the cohesion of the group and its mission.

- Role model: is defined as a guide; they are people showing the right path to be followed, through their actions and behaviors. It is a huge responsibility and a great opportunity to demonstrate their attitudes and skills. They can demonstrate such using a suitable treatment with the patient, excellent academic foundation, and good relationships.
- Counsellor: young interns and residents come daily to the surgeon with conflicts, patient care questions, personal problems, etc. In these situations, the surgeon should be a director and confidant. He/she should be affable, confident ear, who can provide advice on mental and physical health for the residents. Also, he/she helps monitor the stress level of the residents.
- It is the right program director to indicate the stress level of the residents; remember the old phrase of "praise in public and criticize in private". Feedback should attentively, timely, and honest, but critical. Compliments are an effective way to encourage positive behavior, academic, interpersonal, and professional effort among residents.

CONCLUSIONS

In conclusion here are some final tips for excellent leadership development for surgeons:

1. Be seen as someone approachable and trustworthy; residents gain a better understanding as people.
2. Time Management: schedule daily activities; new things appear daily, so the surgeon should learn to prioritize the moment they happen.
3. Surgeons must take time for personal growth and professional development.
4. Surgeons must create a relationship with their boss, additional close work with the program director.

Limitations of this Study

Since this is a systematic literature review, therefore, the main limitation of this study is that it lacks primary research. This is a purely secondary research study although the research reviewed in this review does contain primary research evidence.

Also, the author of this review could only conduct searches in only three databases. Another limitation of this review is that it includes studies in English only and therefore studies published in another language have been excluded.

The scope of the review is also limited because it focuses on the leadership skills of surgeons only and does not focus on the leadership skills of other staff in the operating room. Although there are several limitations in this review yet as explained in previous sections the search strategy is comprehensive and systematic which ensures reliability and validity of the results and findings.

Implications of this review

The main implication of this review is for surgeons and students. They can understand the importance of leadership skills and include the development of leadership skills in their development plans.

Besides, the management and administration of hospitals can also benefit from this review and motivate surgeons and other staff to develop leadership skills and ultimately maximize the quality of care and patients' safety in their hospitals.

The review stresses the importance of leadership skills and therefore it recommends that administrations should plan and implement training courses for surgeons and OR staff to enhance their leadership skills.

Maintenance pharmacologic therapies for opioid use disorders: beyond opioid agonists

Octavian Vasiliu[1]

Abstract: *Opioid use disorder is a worldwide challenge for an increasing number of patients, and still the therapeutic options presented in clinical guidelines for this condition are very few. The first line pharmacological therapies for opioid use disorder continue to be opioid agonists as substitution treatment, but the need to find new treatments without the effect of prolonging opioid dependence become more and more obvious. This systematic review presents the most supported by evidence pharmacological agents that can be used as monotherapy for opioid use disorder patients (i.e., naltrexone, extended release/implant and oral formulation), or as adjuvants to substitution therapy (e.g. olanzapine for aggressive behaviours, memantine or dextromethorphan for reducing inflammatory processes related to opioid use). More good quality data derived from larger, well designed trials are needed in order to find solid recommendations for non-opioid agonists in the treatment of opioid use disorder.*

Keywords*: opioid use disorder, naltrexone, memantine, dextromethorphan, olanzapine, maintenance treatment*

INTRODUCTION

The importance of opioid dependence could not be overemphasized, and during the last decade a continuously increasing number of alerts have appeared both in public media and scientific environment regarding the negative functional impact, increasing societal costs and mortality risk associated with this pathology.

Opioid dependence is a significant contributor to the global disease burden, as between 24 and 35 million people globally used an illicite drug from this category in 2010 [1,2]. North America, Eastern Europe and Southern sub-Saharan Africa are the most strongly affected by the premature mortality related to opioid use disorder [1]. United Nations Office on Drugs and Crime 2017 Report shows an overall increase of the heroin and synthetic opioids use (oxycodone, hydrocodone, tramadol, and fentanyl) since 2009 and the trend to more diversification of the opioid market [3]. Disability-adjusted life years (DALY) attributable to opioid dependence in 2015 reached the value of 12 million, or 70% of the global burden of disease attributable to drug use disorder [4]. Relapse rate after detoxification is very high, ranging from 72% to 88% after 12-36 months [5].

[1] Psychiatry Department, „Dr. Carol Davila" University Emergency Central Military Hospital, Bucharest

Given consideration to the importance of opioid use disorder both at individual and societal level, worldwide efforts have been constantly made in order to find treatments able to prevent opioid use relapse and to maintain patients in remission as long as possible. The most validated treatments for the maintenance phase are methadone and buprenorphine, both with agonist actions at μ-opioid receptors (the first being a partial agonist, while the second is a full agonist). Unfortunately, due to their mechanism of action, both these drugs have abuse potential (less in case of buprenorphine) and associate withdrawal symptoms (although milder than in case of heroin or morphine). Therefore, the need to find non-addictive agents which can be used during the maintenance phase is considered urgent.

OBJECTIVE AND METHODS

This systematic literature review has as primary objective finding non-opioid agonist treatments for the maintenance phase in opioid use disorder patients, based on good quality data. The secondary objective is to formulate evidence-based recommendations for this indication, starting from existing data in the literature.

Table 1. Inclusion/exclusion criteria.

Operational criteria	Inclusion criteria	Exclusion criteria
Population	Minimum age for inclusion was 18 years, no superior age limit was established. The main diagnosis was opioid use disorder. Secondary diagnoses were allowed, if the study design permitted statistical analysis for at least one outcome regarding opioid use disorder. Diagnosis was established according to DSM-IV, IV TR, 5 or ICD-10 criteria.	Patients under age of 18. Presence of severe somatic or psychiatric co-morbidities that may have impact over patients' outcomes, or due to their treatment may lead to confusion about the outcome by pharmacokinetic or pharmacodynamic interactions.
Intervention	Any pharmacological agent without agonism (either partial or complete) over opioid receptors, either as add-on or as monotherapy. Combined pharmacological and psychological treatment. Treatment duration over 4 weeks.	Psychotherapy or psychological counselling as only type of intervention. Non-pharmacological and non-psychotherapeutical interventions, OTC, investigational products used in phase I, II or III clinical trials.
Environment	Inpatients, outpatients. Hospitals, day care, special care, intermediate care units. Carceral environment.	Unspecified environment.
Primary and secondary outcomes	Changes in opioid use- related parameters, e.g. days of abstinence, number of toxicology tests negative, rate of rehospitalisation for opioid consumption. At least one outcome is related to the opioid use.	All trials with outcomes not related to the severity of opioid use disorder.
Study design	Prospective or retrospective clinical trials. Randomized, open label, single blind, or double blind. Case control studies. Epidemiological studies. Observational trials.	Trials with unspecified or insufficiently specified design. Variables referring to opioid use disorder were not included in statistical analysis, or not presented in the published paper. Systematic review, narrative reviews, meta-analyses, case reports, case series.
Language	English, French, German, Russian	Any other language, except for those already specified.

Methods were based on the qualitative review of data found in the main electronic databases- PubMed, Complete MEDLINE, EMBASE, Cumulative Index to Nursing and Allied Health Literature (CINAHL), National Library of Medicine and the National Institute of Health (NCBI), PsychInfo and Thomson Reuters/Web of Science. All clinical trials and epidemiological studies published between 1998 and 2018 in English, French, German, and Russian were included in the primary review. The search paradigm used was „opioid dependence", „opiate dependence", „opioid/opiate use disorder", combined with „non-opioid agonists" or „non-opioid pharmacological treatment". This literature review is based on Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA-P) principles of research [6].

Inclusion and exclusion criteria were applied to all papers found during primary search (table 1).

Therapeutic intervention was focused on drugs with non-opioid agonistic properties. If any psycho-therapeutic intervention was administered, than it was only as an add-on to the pharmacologic management, and not the main method of treatment. Because this review was focused on maintenance therapy, brief interventions were not included. The outcomes of therapeutic intervention had to be periodically evaluated, and statistically analysed. Only trial which produced inferential, statistically-based data were included in the final step of the review.

During the secondary analysis, papers were reviewed and their results were analyzed. Only papers to which full text was found were included in the final analysis.

All studies were ranked according to their level of significance (LOS). This level was determined based on the quality of the study design: (5) double-blind randomized controlled trial, with/without an active comparator/placebo; (4) single-blind trials, with/ without an active comparator/placebo; (3) open-label trials with/without an active comparator; (2) retrospective studies, observational trials; (1) any other study design.

GRADE recommendations for the level of evidence [7] were formulated based on the evidence found in the secondary analysis. GRADE recommendations included 5 levels: A= high quality= future research are very unlikely to change the validity of these recommendations; B= moderate quality= future research is likely to have an important impact on the appreciation of the recommendations; C=low quality= it is very likely that future research will have an important impact over the confidence in the estimate of effect and is likely to change the recommendations; D= very low quality= any estimate of the effect is very uncertain. Intermediate steps (+ or -) represent nuances of the recommendations based on the quality of trials and tolerability of intervention, as resulted from these trials [7].

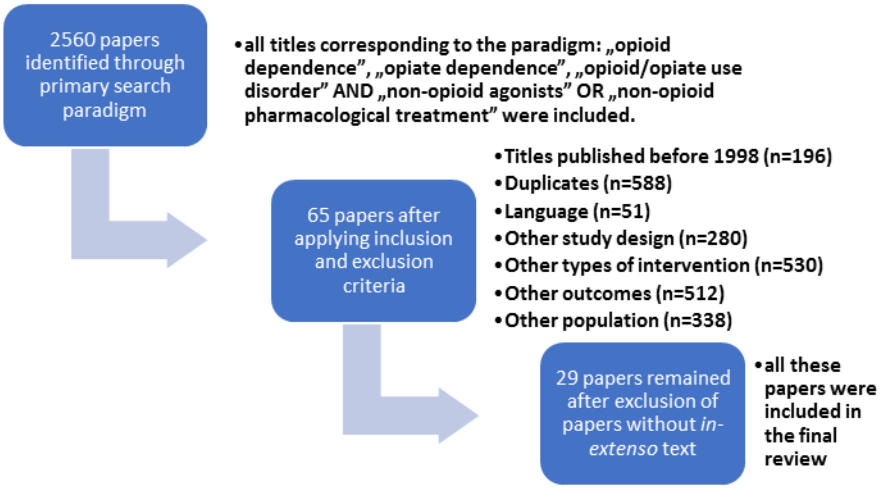
RESULTS

After the primary search 2560 papers surfaced, but only 65 remained when the inclusion and exclusion criteria were applied (figure 1). A number of papers were excluded because full text was not found, so that 29 studies remained to be reviewed in the final step. All trials included in the secondary review are presented in table 2.

These 29 trials included in the secondary analysis had a total number number of participants of 3,159, and a mean LOS of 3.58. A number of 13 trials were found to be high quality designed trials (LOS=5), meaning double-blind, either placebo-controlled or with an active comparator, randomized clinical trials.

Analysis of interventions corresponding to the inclusion/exclusion criteria previously mentioned showed that non-opioid agonist drugs used in the maintenance phase in patients with opioid use disorder who have been previously detoxified were: (1) naltrexone implant; (2) oral naltrexone; (3) topiramate; (4) memantine; (5) dextromethorphan; (6) dronabinol; (7) olanzapine; (8) baclofen; (9) ibudilast; (10) buspirone; (11) sodium valproate; (12) fluoxetine; (13) paroxetine; (14) clonazepam; (15) gabapentin. The last five drugs were used only in combination with another active medication or as active comparators, so they were not evaluated separately in this review.

Figure 1: Stepwise filtration of titles found during electronic databases search



2560 papers identified through primary search paradigm
•all titles corresponding to the paradigm: „opioid dependence", „opiate dependence", „opioid/opiate use disorder" AND „non-opioid agonists" OR „non-opioid pharmacological treatment" were included.
65 papers after applying inclusion and exclusion criteria
•Titles published before 1998 (n=196)
•Duplicates (n=588)
•Language (n=51)
•Other study design (n=280)
•Other types of intervention (n=530)
•Other outcomes (n=512)

Naltrexone was the most investigated non-opioid agonist medication for the maintenance therapy in opioid use disorder, and 15 relevant trials focus on this drug's efficacy have been found during the secondary search. Naltrexone is an opioid antagonist, and both the parent drug and its active metabolite (6β-naltrexol) are competitive antagonists of the μ-, and to a lesser extend to κ- and δ-opioid receptor (10-25 times lower affinity for κ- and δ-receptors compared to the μ-receptors) [8]. Because oral naltrexone is extensively metabolized during first-pass metabolism, and because therapeutic adherence of opioid users is known to be very low, various implant formulations of this pharmacological agent have been developed.

Oral formulation of naltrexone has been investigated in comparison with buprenorphine/naloxone in the post-detox phase [9], methadone in stabilized patients [10], buprenorphine and placebo in detoxified patients [11], methadone in opioid dependent patients who were stablized on methadone maintenance treatment for controlling depressive and anxiety symptoms [12]. Oral naltrexone as monotherapy was compared with naltrexone plus gabapentin (1200 mg/day) for the management of muscle pain and craving [13], and naltrexone plus placebo was compared with naltrexone plus sertraline for controlling depression severity and opioid craving [14]. Another trial compared naltrexone (50 mg/day) + fluoxetine (20 mg/day) with naltrexone + placebo, fluoxetine + placebo, or placebo for 6 months plus psychotherapy for all groups for the monitoring of remission rate during 6 months [15]. The mean LOS of these studies was 3.85, and an overall number of 657 patients were included.

These trials supported a moderate efficacy and tolerability of oral naltrexone: buprenorphine/naloxone was superior to naloxone in the reduction of opioid-positive urine test and preserving patients participation in the treatment [6], naltrexone induced similar weight gain during 6 months of treatment when compared to methadone [16], naltrexone may improve depression in patients with opioid use disorder at 6 months [12], and naltrexone was inferior to buprenorphine (not statistically significant) in several outcomes regarding the rate of relapse in detoxified heroin dependent patients [11].

Naltrexone plus fluoxetine and individual psychotherapy has been proven a useful combination especially in women with heroin dependence, because it increased the remission rate and maintenance of remission in this population [15]. Naltrexone plus gabapentin improved muscle pain and psychological dependence severity in patients dependent on pentazocine [13]. Naltrexone plus sertraline was a well-tolerated combination and increased on short-term treatment retention of recently non-depressed opioid abstinent patients, but the difference between this combo and naltrexone alone disappeared in time [14].

Naltrexone extended-release has been investigated in comparison with buprenorphine/naloxone [16], treatment as usual [5], oral naltrexone plus psychosocial therapy [17], and methadone [18]. Naltrexone implant was investigated also in several trials as single pharmacological agent, without an active comparator [19-22]. The mean LOS of these trials was 2.8, and the global number of participants was 1982.

The overall efficacy of naltrexone extended-release was good, although data are derived from poor and medium-quality designed trials. Its efficacy and tolerability were similar to buprenorphine/naltrexone in patients who wanted to switch from this combination of drugs to naltrexone implant [16], and it induced a lower rate of relapse when compared to treatment as usual, at least on short-term [23]. Heroin dependent patients who received extended release formulation of naltrexone had better outcomes than those treated with oral formulation of the same drug [17], and naltrexone implants but not methadone were associated with long-term benefits in decreasing opioid-related hospital morbidity [18].

In trials without an active comparator, naltrexone extended-release was efficient in preventing opioid overdose [22], improved depression severity at 4 weeks post-baseline, but it may also be responsible of worsening late insomnia [21], improved quality of life, rate of retention, opioid-negative urines, opioid craving, and rate of re-employment [20]. Also, naltrexone plus psychological counselling improved the acceptance of opioid dependence pharmacotherapy and prolonged the duration of abstinence to opioids, when compared to placebo plus counselling [19].

Topiramate is an anticonvulsant with GABA-enhancing properties and AMPA and kainate-inhibitory actions, involved in the modulation of extracellular dopamine release in the mesocortical and limbic system dopaminergic system, properties which recommended it as a potential treatment for cocaine dependence [24]. Patients with opioid use disorder who presented also cocaine dependence did not benefit from the addition of topiramate to their methadone maintenance therapy, because no difference to placebo could be found after 12 weeks [25].

Ibudilast is an anti-inflammatory drug with phosphodiesterase inhibition properties (especially PDE4) which has been associated in animal studies with the capacity of alterating several opioid-mediated effects [26, 27]. When compared with placebo in a 6-week RCT in patients detoxified from morphine, ibudilast treated patients presented lower rates of drug liking (oxycodone), lower craving to heroin/ tobacco/cocaine and lower subjective ratings of pain vs. placebo [26].

Memantine is a noncompetitive NMDA-receptor antagonist that blocks the effects of excessive concentrations of glutamate, currently used for Alzheimer Disease- related neurocognitive disorder and researched intensively for other dementias, ADHD, and as an agent able to reverse tolerance to opioids [28]. Memantine was administered in patients who were on buprenorphine/naloxone maintenance treatment, and compared to placebo [29], or in patients who were on methadone-maintenance-therapy, compared to placebo plus methadone-maintenance therapy [30, 31]. Memantine was also investigated as maintenance treatment in detoxified non-treatment seeker heroin dependent patients during 8 weeks of in-patient regimen [32].

These trials investigating the efficacy of mematine had a mean LOS of 4.25, and an overall number of 350 participants. It can be observed that the quality of trials focused on memantine efficacy was higher than previously mentioned research for other investigational products.

Memantine has been proven as a useful adjunctive medication for patients treated with buprenorphine/naloxone and it may provide an easier transition to buprenorphine-free therapeutic regimen [29]. Low dose memantine attenuated chronic opioid-dependence-induced cognitive impairment, decreased the daily dose of methadone, and had positive effect over probably NMDA-mediated inflammatory processes [30, 31]. Memantine decreased the subjective, but not the reinforcing effects of heroin in non-treatment seeker heroin-dependent patients [32].

Dronabinol is a synthetic form of 9-tetrahydro-cannabinol, with similar affinity for cannabinoid 1 and 2 receptors, currently approved for use in anorexia associated with weight loss in AIDS and for the treatment of nausea associated with chemotherapy resistant to other anti-nausea treatments [33]. A double-blind, placebo-controlled RCT investigated the effects of dronabinol in patients with naltrexone extended release and a significant effect of this drug in decreasing the severity of opiate withdrawal has been proven [34].

Dextromethorphan is an antitussive drug with N-methyl-D-aspartate (NMDA) receptor antagonist properties, involved also in protecting monoaminergic neurons against inflammation-mediated degeneration [35, 36]. Chronic opioid administration produces systemic inflammation, and for this reason the use of a drug with anti-inflammatory properties seems to be granted [37]. Based on its neuroprotective and anti-inflammatory properties, dextromethorphan was investigated as adjunctive agent in patients with opioid use disorder. Dextromethorphan 60 mg/day and 120 mg/day were compared with placebo as adjunctive to methadone treatment in opioid-dependent patients [37, 38], and in another trial dextromethorphan 240 mg/day was compared with placebo in methadone-stabilized patients [39].

These trials with dextromethorphan had a mean LOS of 5, and a total of 268 patients.

Dextromethorphan was useful in low doses as adjuvant treatment in methadone-treated patients both at inflammatory level and clinical level [37, 38], but in another trial the difference versus placebo was not significant in the otcome defined as mean methadone consumption [39]. The quality of life was superior in patients who reeived dextromethorphan as adjuvant to methadone versus placebo plus methadone [39].

Olanzapine is an atypical antipsychotic investigated in patients with opioid dependence who were on substitution therapy, as a drug targeting the aggresive behavior [40, 41]. The mean LOS of these trials was 3.5, and the total number of participants was 268.

In the first trial, olanzapine (2.5-15 mg) was compared with sodium valproate (600-1000 mg) in patients stabilized on methadone, and olanzapine was slightly superior in controlling aggressivity but did not differed from valproate in reducing the number of positive urine samples [40]. In the second, smaller-sample size, olanzapine was compared to fluoxetine/paroxetine and clonazepam and reduced aggressive/hostile behavior in heroin addicted patients undergoing substitution therapy [41]. In this second trial, olanzapine was superior to its comparators in the direct aggressiveness, overall hostility, verbal aggressiveness, and aggressive incidents; also, 70% of the completers achieved full remission, without significant differences between groups [41].

Buspirone is a non-benzodiazepine anxiolytic which possesses 5HT1A agonistic properties, acting as full agonist at 5HT1A presynaptic receptors and partial agonist at postsynaptic 5HT1A receptors [42]. A single trial that compared buspirone with placebo in patients with anxiety undergoing methadone therapy has been identified during the literature review [43]. Buspirone had no significant efficacy over anxiety symptoms in these patients, but it decreased depression severity and slowed down the return to substance abuse [43].

Baclofen is a GABA-B receptor agonist that may be helpful in promoting abstinence from a variety of drugs [44]. A double-blind, placebo-controlled, 12-week RCT with a LOS of 3, which included 40 patients with opioid dependence, recently detoxified, found a significantly better treatment retention in the baclofen-treated patients (60 mg/day) [45]. This trial had a small sample size and a high attrition rate, which make difficult to generalize its results.

Table 2. Trials focused on non-opioid agonist therapies during the post-detoxification phase in patients with opioid use disorder

Authors	Study design, description of therapeutic intervention	Patients	Primary outcomes	Results	Conclusion	LOS
Pirnia B, Soleimani AA, Malekanmehr P, et al. [25]	Placebo-controlled RCT; topiramate (25-300 mg/day), 12 weeks, escalating doses; patients were treated also with methadone 20-140 mg/day and brief behavioral compliance enhancement treatment for cocaine dependence.	n=50 patients with dual cocaine and opiates dependence	Weekly urine drug screens.	Topiramate was no better than placebo in reducing cocaine use, but was superior to placebo in reducing cocaine craving.	The efficacy of topiramate in cocaine use reduction in patients with dual cocaine and opiates dependence was not supported.	5
Solli KK, Latif ZE, Opheim A, et al. [16]	Prospective cohort study, naltrexone-extended release vs. buprenorphine-naloxone 3 month + participants' choice of study medication for an additional 9 months; the active drug was administered every 4 weeks (380 mg).	n=54 opioid-dependent adults continuing naltrexone-extended release and n=63 opioid dependents inducted on the same treatment	Use of heroin and other illicit substances, opioid craving, treatment satisfaction, treatment retention, adverse events, addiction-related problems	Follow-up after 9 months showed completion rates of 51.9% among participants continuing naltrexone-extended release in the follow-up and 47.6% among those inducted on the active treatment, with opioid abstinence rates of 53.7 and 44.4%, respectively.	Opioid-dependent individuals who elect to switch from buprenorphine-naltrexone after 3 months to extended release naltrexone 9 months were experiencing similar results (treatment completion and abstinence rates) and similar rate of adverse events to those who had been on extended-release naltrexone from the start.	4
Metz VE, Jones JD, Manubay J, et al. [26]	6-week RCT focused on ibudilast (a nonselective phosphodiesterase inhibitor) effects over craving, reinforcing, analgesic effects of oxycodone in human volunteers diagnosed with opioid dependence; patients received maintenance treatment with ibudilast (50 mg bid) or placebo	n=11 patients detoxified from morphine addiction	VAS for measurement of subjective effects of oxycodone.	Patients receiving active ibudilast presented decreased rates of drug liking after 15 mg of oxycodone; heroin/ tobacco/cocaine craving was reduced under active ibudilast vs. placebo; mean subjective ratings of pain were lower in the active ibudilast condition.	Ibudilast may be useful in treating opioid use disorder and may enhance the analgesic effects of oxycodone.	3

Authors	Study design, description of therapeutic intervention	Patients	Primary outcomes	Results	Conclusion	LOS
Earley PH, Zummo J, Memisoglu A, et al. [20]	Single-arm, multisite, open-label study; extended release naltrexone injections for up to 24 months, combined with counselling via intensive outpatient substance abuse treatment programs.	n=38 enrolled opioid-dependent healthcare professionals who had been detoxified for at least 2 weeks	Opioid drug tests monthly, measurements for quality of life, opioid craving, and treatment satisfaction	At 24 months, mean opioid craving fell by 45.2% and quality of life (SF-36) -mental component score improved by 31.1% from baseline; of the 22 unemployed subjects at baseline, 45.5% improved employment status at 24 months.	Long-term extended release naltrexone was associated with better quality of life, rates of retention, opioid-negative urines, opioid-craving reduction, re-employment	3
Lee JD, Friedmann PD, Kinlock TW, et al. [23]	Open-label RCT, 24-week extended-release naltrexone vs. usual treatment (brief counseling and referrals for community treatment programs);	n=308 criminal justice offenders with history of opioid dependence, abstinent from opioids at the time of randomization	Time to an opioid-relapse event (defined as 10 or more days of opioid use in a 28-day period).	Participants assigned to extended-release naltrexone had a longer time to relapse than did those who received usual treatment, lower rate of relapse, and higher rate of opioid-negative urine samples. After one year, the rates of opioid-negative urine samples were equal. During one year, there were no overdose events in the extended-release naltrexone treated participants, while in the usual-treatment group there were 7 cases.	Extended-release naltrexone was associated with a rate of opioid relapse lower than that with usual treatment, but after one year the protective effects waned.	3
Mokri A, Chwarski MC, Taherinakhost H, Schottenfeld RS [9]	Single-site, two-parallel groups, double-blind RCT, 12-week; oral naltrexone vs. buprenorphine/ naloxone.	n=102 participants with opioid use disorder in the post-detox phase	Initial duration of opioid abstinence (urine toxicology tests).	Mean number of days of initial duration of verified abstinence was higher with buprenorphine/naloxone (p=0.205); mean number of opioid-negative urine tests was higher in the buprenorphine/ naloxone-treated subjects (p=0.049); the mean number in treatment was also greater in buprenorphine/naloxone group (p=0.013); the rate of sustained, 12-week opioid abstinence was double in the buprenorphine/ naloxone group.	Sublingual buprenorphine/ naloxone was associated with a greater number of opioid-negative urine tests and treatment retention, but not significantly greater initial abstinence duration or proportions with sustained abstinence.	5

Authors	Study design, description of therapeutic intervention	Patients	Primary outcomes	Results	Conclusion	LOS
Gonzalez G, DiGirolamo G, Romero-Gonzalez M, et al. [29]	Double-blind placebo-controlled RCT, 13 weeks; patients already received treatment with buprenorphine/naloxone 16/4 mg/day and they were randomized to memantine 15 mg or 30 mg vs. placebo.	n=80 young adults with opioid dependence	Change in the weekly mean proportion of opioid use, and cumulative abstinence rates after rapid buprenorphine discontinuation at week 9	Memantine 30 mg/day significantly improved short-term treatment with buprenorphine/ naloxone by reducing relapse and opioid use after buprenorphine discontinuation, during the last 2 weeks of study participation.	Memantine could be an useful adjunctive treatment at 30 mg daily for patients treated with buprenorphine/ naloxone and helpful in the transition to buprenorphine-free therapeutic regimen.	5
Bisaga A, Sullivan MA, Glass A, et al. [34]	Double-blind RCT, dronabinol 30 mg/day (n=40) vs. placebo (n=20); patient underwent inpatient detoxification for opioid dependence and extended-release naltrexone induction; dronabinol was administered while inpatient and 5 weeks afterwards.	n=60 patients recently de-toxified from opioids	Severity of opioid withdrawal and retention in treatment.	The severity of opioid withdrawal during inpatient phase was lower in the dronabinol group vs. placebo; rates of successful induction onto extended release naltrexone and completion of treatment were not significantly superior for dronabinol vs. placebo.	Dronabinol reduced the severity of opiate witdrawal but had no effect on rates of extended-release naltrexone treatment induction and retention.	5
Chang YH, Chen SL, Lee SY, et al. [30]	RCT, memantine plus methadone-maintenance-therapy (n_1=57) vs. placebo plus methadone-maintenance therapy (n_2=77); healthy controls were matched with methadone-treated group; 12 weeks duration of monitoring.	n=134 patients stabilized on methadone	Cognitive performances	Both treatment groups showed improvements in their cognitive performances. Memantine add-on was superior to placebo in the post-treatment cognitive improvement.	Low-dose memantine (5 mg/day) may attenuate chronic opioid-dependence-induced cognitive decline.	5
Lee SY, Chen SL, Chang YH, et al. [37,38]	12-week RCT, dextrometorphan 60 mg/day (n_1=65), 120 mg/day (n_2=65) vs. placebo (n_3=66) as adjunctive to methadone treatment in opioid-dependent patients.	n=196 opioid dependents	Methadone dose required, plasma morphine level, retention in treatment.	Patients who received 60 mg/day dextromethorphan had significantly longer treatment retention and lower plasma morphine levels than did the placebo group. Plasma TNF-alpha was significantly decreased in the 60 mg dextromethorphan group compared to placebo.	Low dose dextromethorphan is useful as concomitant therapy in methadone-treated patients both at the pathogenic-inflammatory level, and at the clinical level.	5

Authors	Study design, description of therapeutic intervention	Patients	Primary outcomes	Results	Conclusion	LOS
Lee SY, Chen SL, Chang YH, et al. [31]	Double-blind RCT, placebo-controlled, 12-week duration; memantine (5 mg/day) (n_1=53) vs. placebo (n_2=75); patients with opioid dependence undergoing methadone maintenance therapy.	n=128 patients stabilized on methadone	Inflammatory bio-markers, overall dose of methadone	Memantine-treated patients required a somewhat lower methadone dose than did placebo-group (p=0.039), and they also had significantly lower plasma TNF-α and higher TGF-β1 levels.	Low-dose memantine may help patients during methadone substitution treatment because of the overall methadone dose decrease and positive impact over inflammatory process possible related to the NMDA-receptors.	5
Krupitsky E, Nunes EV, Ling W, et al. [19]	Double-blind, placebo-controlled multicentric RCT, 24 weeks; 380 mg extended-release naltrexone vs. placebo; counselling sessions were provided for both groups.	n=250 patients with opioid dependence, who underwent detoxification	Confirmed abstinence (urine drug tests and self-report).	Extended-release naltrexone-treated patients had significantly longer periods of confirmed abstinence (p=0.0002), more opioid-free days (p=0.0004), less craving (p<0.0001), more treatment-retention (p=0.0042).	Extended-release naltrexone in conjunction with psychosocial treatment improve the acceptance of opioid dependence pharmacotherapy and prolongs the duration of abstinence to opioids.	5
Krupitskii EM, Zvartau EE, Tsoi-Podosenin MV, et al. [15]	RCT, patients were randomized on naltrexone (50 mg/day) + fluoxetine (20 mg/day), naltrexone + placebo, fluoxetine + placebo, or placebo for 6 months; individual psychotherapy for the maintenance of remission was applied for all gropus (one session).	n=280 patients with heroin addiction	Remission rate, maintenance of remission	Naltrexone + fluoxetine was more effective than fluoxetine + placebo (p<0.01) and placebo (p<0.001) in the remission percentage. Naltrexone was superior to placebo and fluoxetine in the efficacy of maintenance of remission and preventing relapse in patients with heroin addiction. The combination of naltrexone and fluoxetine was more effective compared to naltrexone monotherapy only in women.	Naltrexone and fluoxetine could be useful in patients with heroin dependence, especially in women.	5

Authors	Study design, description of therapeutic intervention	Patients	Primary outcomes	Results	Conclusion	LOS
Zarghami M, Sheikhmoonesi F, Ala S, et al. [40]	12-week RCT, olanzapine (2.5-15 mg) vs. sodium valproate (600-1000 mg).	n=201 patients on methadone maintenance treatment	Aggressive behavior, urine toxicology.	Olanzapine and sodium valproate reduced the overt aggression and subscales of irritability, aggression, and suicidality. Olanzapine-treated patients presented more improvement in aggressivity. The percentage of positive urine samples (morphine, cannabis, methamphetamine) were not significantly different between the study groups.	Olanzapine and sodium valproate may be useful as adjunctive agent in decreasing aggressive behavior in heroin dependent individuals during methadone substitution treatment, with a slightly superior effect of olanzapine.	4
Salehi M, Zargar A, Ramezani MA [39]	Double-blind RCT, dextromethorphan vs. placebo; 6-month follow-up.	n=72 opiate abusers with methadone maintenance therapy	Methadone consumption dosage, quality of life, withdrawal symptoms.	The mean methadone consumption in the dextromethorphan-treated patients vs. control group were 62.7 mg/day vs. 70.4 mg/day. Total mean score of the quality of life was superior in the intervention group ($p>0.05$).	Dextromethorphan might be useful for opioid dependence treatment, but the differences vs. placebo were not significant.	5
Brooks AC, Comer SD, Sullivan MA, et al. [17]	Quasy-experimental comparison, long-acting injectable naltrexone (n_1=42) vs. oral naltrexone (n_2=69). Psychosocial therapy was also initiated for these patients.	n=101 patients on naltrexone	Days retained in treatment, severity of drug use	Long-acting injectable naltrexone had been associated with better outcome than oral naltrexone on days retained in treatment and other measurements for opiate use, while still other measurements for opiate use were not significantly different; heroin users with more severe baseline use showed better retention with oral naltrexone maintenance therapy, while less severe heroin users evidenced better outcomes when treated with long-acting injectable naltrexone.	Superior outcomes for heroin-dependents who received long-acting injectable naltrexone compared to oral naltrexone.	2

Authors	Study design, description of therapeutic intervention	Patients	Primary outcomes	Results	Conclusion	LOS
Mysels DJ, Cheng WY, Nunes EV, Sullivan MA [21]	Prospective evaluation using Hamilton Depression Rating Scale in patients treated with naltrexone depot maintenance and relapse prevention therapy; 2 and 4 -week post-baseline evaluations.	n=34 patients on naltrexone	Depression severity	Significant improvement of depression scores after 4 weeks post-baseline ($p<0.0004$), somatic and cognitive-affective subscales scores significantly decline; late insomnia increased significantly at 2 weeks post-baseline.	Naltrexone induction and maintenance does not worsen depression, but it may cause sleep impairments	2
Myesels DJ, Vosburg SK, Benga I, et al. [10]	Retrospective chart review; patients were maintained on methadone (n=16) or naltrexone (n=20);	n=36 opiate dependent patients stabilized on pharmacological treatment	Change in body weight from baseline to 3 months and 6 months into treatment.	No difference in weight was detected at baseline, 3 or 6 months between the two treatment groups.	No statistically difference over the weight between methadone and naltrexone maintenance treatment.	2
Schottenfeld RS, Chawarski MC, Mazlan M [11]	Double-blind RCT, 24 weeks; oral naltrexone vs. buprenorphine vs. placebo	n=126 detoxified heroin-dependent patients	Days to first heroin use (urine drug tests), days to heroin relapse, maximum consecutive days of heroin abstinence, reductions in HIV risk behaviours over 6 months.	Days to first heroin use, days to heroin relapse (3 consecutive positive tests), and maximum consecutive days abstinent had all supported the superiority of buprenorphine (significant to placebo). Differences between buprenorphine and naltrexone were not significant for days to heroin relapse and maximum consecutive days abstinent. Differences between naltrexone and placebo were not significant for any outcomes. HIV risk behaviours were significantly reduced by all three treatments.	Buprenorphine was superior to naltrexone, although for the most variables monitored the differences were not statistically significant.	5
Ngo HT, Tait RJ, Hulse GK [18]	Retrospective longitudinal follow-up; methadone (n_1=522) or naltrexone implant (n_2=314) as maintenance treatment for opioid- dependent patients. Evaluations at 6 months and 3.5 years post-treatment.	n=836 patients treated for opioid dependence	Hospital admissions rates, adjusted changes in risks and rates of overdose-related and non-overdose-related hospital morbidity associated with opioid vs. nonopioid drugs.	Naltrexone implant decreased risk for overdose and non-overdose-related events at 3.5 years, but not methadone; 5 drug-related deaths after methadone and 1 after naltrexone implantation.	Naltrexone implants, but not methadone, has been associated with long-term benefits in decreasing opioid-related hospital morbidity.	2

Authors	Study design, description of therapeutic intervention	Patients	Primary outcomes	Results	Conclusion	LOS
Gerra G, Di Petta G, D'Amore A, et al. [41]	12-week prospective, observational trial; open-label study; olanzapine vs. fluoxetine/ paroxetine+ clonazepam for controlling aggressiveness.	n=67 patients with heroin dependence undergoing substitution therapy	Hostility scores, incidence rates of aggressive incidents and attacks.	Direct aggressiveness, overall hostility scores, verbal aggressiveness scores, aggressive incidents rates were significantly lower compared to baseline in patients treated with olanzapine who comple-ted the treatment. Among completers, almost 70% achieved full substance abuse remission, 30% partial substance abuse remi-ssion, without signifycant differences between groups.	Olanzapine may be useful as adjunctive treatment in reducing aggressive/hostile behavior in heroin addicted patients who undergo maintenance substitution therapy.	3
Dean AJ, Saunders JB, Jones RT, et al. [12]	Open-label RCT, naltrexone 50 mg/day (n_1=42) vs. methadone (n_2=38) in opioid dependent patients who were stablized on methadone maintenance treatment; 6-month duration.	n=80 patients stabilized on methadone	Depressive symptoms severity, anxiety symptoms severity.	Patients who received naltrexone did not exhibit worsening of depressive symptoms; in patients attending follow-up assessments, those who received naltrexone presented an improvement in depression over time, compared to the control group; adherence to naltrexone correlated with lower depression severity scores.	Naltrexone has a positive impact over depressive symptoms during maintenance treatment in opioid dependent patients.	3
Hulse GK, Tait RJ, Comer SD, et al. [22]	Cohort study, pre-post design, data were prospectively collected; patients were evaluated before and after treatment with a sustained release naltrexone implant; a subgroup (n=146) had previously received treatment with oral naltrexone.	n=361 heroin dependent persons	Primary outcome was overdose events.	21 overdoses involving 20 persons in the 6 months pre-treatment; none was observed in the 6 months post-treatment; blood naltrexone levels at or above 3 ng/ml for approximately 6 months after injecttion; reduced number of opioid overdoses were also observed 7-12 months after implant; for those previously treated with oral naltrexone, more opioid overdoses occured in both 6-month prior to and after oral compared to the 6-month post-implant treatment.	Sustained-release naltrexone implant is efficient in preventing opioid overdose.	2

Authors	Study design, description of therapeutic intervention	Patients	Primary outcomes	Results	Conclusion	LOS
Comer SD, Sullivan MA [32]	Detoxified, non-treatment-seeker-heroin dependent patients; 8 weeks; 0, 30, 60 mg/day memantine as maintenance treatment; intranasal heroin (0, 12.5, 50 mg); inpatient regimen.	n=8 patients with heroin dependence	Subjective ratings of drug quality, liking, willingness to pay for drugs, craving.	Memantine produced modest reductions in subjective ratings of drug quality, liking, willingness to pay for the drug, and craving for heroin. It had little influence over the reinforcing heroin effects.	Memantine could be a useful agent for decreasing the subjective but not the reinforcing effects of heroin.	2
McRae AL, Sonne SC, Brady KT, et al. [43]	RCT, 12-week, placebo-controlled study; patients on methadone who presented also anxiety symptoms; buspirone vs. placebo.	n=36 patients receiving methadone maintenance treatment	Anxiety symptoms	Buspirone did not significantly decrease anxiety symptoms in opioid-dependent patients.	Buspirone had no significant efficacy over anxiety symptoms in subjects undergoing methadone maintenance treatment, but it was associated with reduction in depression scale scores and slower return to substance use.	5
Assadi SM, Radgoodarzi R, Ahmadi-Abhari SA [45]	Double-blind, placebo-controlled, 12-week RCT; patients received fixed-schedule baclofen 60 mg/day or placebo.	n=40 patients with opioid dependence, recently detoxified	The primary outcome was retention in treatment.	Treatment retention was significantly higher in the baclofen group (p=0.01); 30% of patients treated with baclofen completed the trial vs. 10% patients on placebo. The rates of opioid-positive urine samples did not differ significantly between the two groups. Baclofen was superior to placebo in terms of opiate withdrawal syndrome and depressive symptoms. Intensity of opioid craving and self-reported opioid and alcohol use were more favourably influnced by baclofen, although not statistically significant. The drug side effects of the two groups were not significantly different.	Baclofen could be useful in the maintenance treatment of opioid dependence, but the sample size was small, and the attrition rates were high.	5

Authors	Study design, description of therapeutic intervention	Patients	Primary outcomes	Results	Conclusion	LOS
Kumar P, Jain MK [13]	Open label trial; patients received clonidine (for detox) and later naltrexone p.o. (50 mg BD) as maintenance therapy vs. naltrexone plus gabapentin (1200 mg/day) for 3 weeks.	n=20 opioid dependent patients (pentazocine)	Muscle pain and craving (rated on visual-analogue scale), psychological dependence severity.	Patients receiving naltrexone + gabapentin scored significantly lower on both parameters- pain score and craving score (p<0.001), and psychological dependence was significantly lower in this group (p<0.01).	Gabapentin is efficient in controlling muscle aching, and no tolerance effect was observed after 3 weeks. Gabapentin may reduce pain in opioid dependent patients when added to naltrexone, signaling a possible synergistic effect. Gabapentin may help in controlling the opiate craving and potentiated the effect of naltrexone in this regard.	3
Farren CK, O'Malley S [14]	Double-blind, placebo-controlled trial, naltrexone 50 mg qd plus placebo vs. naltrexone 50 mg plus sertraline 50 mg qd; 12-week monitoring duration.	n=13 recently non-depressed abstinent opiate addicts	Depression severity, opiate craving, adverse events	Similar side effect profile in both groups, and similar retention rates. Significant negative correlation between Beck Depression Inventory scores and duration in treatment in the combined therapy group. Opiate craving decreased over time in both groups.	Naltrexone plus sertraline was well tolerated and initially successful in increasing treatment retention, but the difference to the naltrexone alone diminished in time.	4

Based on these results a number of recommendations can be made in patients who need maintenance treatment for opioid use disorder, if a drug without opioid agonistic properties is preferred (table 3). These recommendations have been hierarchized according to the GRADE system [35].

Regarding the limitations of current review it can be mentioned the overall low quality design of the clinical research, only 13 articles included double-blind, controlled, randomized trials. Another limitation is related to the low number of drugs investigated, and except for naltrexone (oral and extended-release), data regarding the efficacy or tolerability of other pharmacological agents were derived from few good quality trials. Only one reviewer was involved in the processing of data collected, so a bias related to this aspect can not be excluded. More research is needed, and larger, well designed trials focused on a more diverse range of drugs are also expected to be launched in order to provide more accurate recommendation in a continuously extending pathology, like the opioid use disorder.

Table 3. Recommendation based on the literature review for patients with opioid use disorder with non-opioid agonist pharmacological agents

Treatment	Clinical trials	Advantages/disadvantages	GRADE recommendations
Naltrexone- oral administration	[9-15]	(+) naltrexone improve depressive symptoms in patients with opioid use disorder at 6 months (+) naltrexone plus fluoxetine and individual psychotherapy has been proven useful in women with heroin dependence (+) naltrexone plus gabapentin improved muscle pain and psychological dependence severity in patients dependent on pentazocine (+) naltrexone plus sertraline increased short-term treatment retention of recently non-depressed opioid abstinent patients (-) buprenorphine/naloxone was superior to naloxone in the reduction of opioid-positive urine test and preserving patients participation in the treatment (-) similar weight gain during 6 months of treatment when compared to methadone (-) naltrexone was inferior to buprenorphine (not statistically significant) in several outcomes regarding the rate of relapse in detoxified heroin dependent patients	B
Naltrexone-extended release	[16-23]	(+) efficacy and tolerability were similar to buprenorphine/naltrexone (+) lower rate of relapse when compared to treatment as usual, at least on short-term (+) better outcomes than those treated with oral formulation of the same drug (+) naltrexone implants but not methadone were associated with long-term benefits in decreasing opioid-related hospital morbidity (+) efficient in preventing opioid overdose (+) improved depression severity at 4 weeks post-baseline (+) improved quality of life, rate of retention, opioid-negative urines, opioid craving, rate of re-employment (+) prolonged the duration of abstinence to opioids, in combination with counselling (-) worsened late insomnia (-) requires implant of the active drug (usually subcutaneous)	B+
Topiramate	[25]	(-) negative results in patients with opioid and cocaine use disorder	D-
Ibudilast	[26]	(+) induced lower rates of drug liking (oxycodone), lower craving to heroin/tobacco/cocaine and lower subjective ratings of pain vs. placebo	C
Memantine	[29-32]	(+) may provide an easier transition to buprenorphine-free therapeutic regimen (+) induced attenuation of chronic opioid-dependence-related cognitive impairment (+) decreased the daily dose of methadone (+) it had positive effect over probably NMDA-mediated inflammatory processes in opioid users (+) it decreased the subjective effects of heroin in chronic users (-) it did not decreased the reinforcing effects of heroin in non-treatment seeker heroin-dependent patients	C+

Treatment	Clinical trials	Advantages/disadvantages	GRADE recommendations
Dronabinol	[34]	(+) it decreased the severity of opioid withdrawal (-) no effect over rates of naltrexone-treatment induction or retention	D
Dextro-methorphan	[37-39]	(+) it was useful in low doses as adjuvant treatment in methadone-treated patients both at inflammatory level and clinical level (+) the quality of life was superior in patients who received dextromethorphan as adjuvant to methadone versus placebo plus methadone (-) the difference versus placebo was not significant in the otcome defined as mean methadone consumption	C
Olanzapine	[40,41]	(+) it reduced direct aggressiveness, overall hostility, verbal aggressiveness, and aggressive incidents (+) improved the rate of treatment retention	C
Buspirone	[43]	(+) positive effect over depressive symptoms associated to methadone maintenance treatment (-) no effect over anxiety	C-
Baclofen	[45]	(+) significantly better treatment retention	C-

From the data collected in this review only extended release naltrexone seems to achieve a B+ level of recommendation, based on 8 trials, and the benefits of using extended-release naltrexone tend to overcome its potential disadvantages in patients with opioid use disorder who underwent successful disintoxication. This naltrexone formulation had positive impact over a large number of outcomes related to opioid use disorder, including rate of relapse, quality of life, opioid-related hospital morbidity, and depressive severity [16-23]. As an alternative, oral naltrexone may be tried, although negative trials exist – level B recommendation, based on 7 trials [9-15]. Naltrexone plus fluoxetine and individual psychotherapy has been proven a useful combination especially in women with heroin dependence [15]. Naltrexone plus gabapentin improved muscle pain and psychological dependence severity in patients dependent on pentazocine [13]. Naltrexone plus sertraline were well-tolerated and increased on short-term treatment retention of recently non-depressed opioid abstinent patients [14].

Memantine has a level C+ recommendation for its use as adjuvant treatment in opioid use disorder because there more data to support its efficacy are needed. Low dose memantine attenuated chronic opioid-dependence-induced cognitive impairment and decreased the daily dose of methadone [30, 31]. However, information have been gathered about its positive effect over cognition, inflammatory processes, and decrease of methadone daily dose [29-32].

Olanzapine may be recommended for controlling aggressivity in patients with opioid use disorder, as adjuvant treatment (level C) [40, 41].

Dextromethorphan was associated with some positive results, although it did not decrease the necessary daily dose of methadone when used as adjuvant agent [37-39]. This drug was however useful in improving both clinical and inflammatory outcomes, and improved patients' quality of life [37-39].

Dronabinol did not prove itself efficient in the maintenance phase of treatment, although it may be of some help in alleviating withdrawal symptoms in opioid users [34].

Data for ibudilast, baclofen, and buspirone are insufficient to allow for stronger recommendations in the targeted population, but further research may change this perspective.

CONCLUSIONS

Data showing a continued increase of illegal opioids use are overwhelming, and it became obvious that clinicians must find new solutions for treating a continuously growing population affected by opioid use disorder. Opioid agonists like buprenorphine and methadone are considered now the first line for treatment of opioid dependent patients, but non-opioid agonist drugs should be investigated more, either as adjuvant agents or as monotherapy. These non-opioid agonist agents can lead to the administration of lower doses of opioid agonists (in case of adjuvant treatment), or even to their complete replacement, in both cases diminishing the risk for a new dependence.

From the data reviewed, extended-release naltrexone is the most supported by evidence recommendation, followed by oral naltrexone, in patients who were successfully detoxified from opioids. Naltrexone had positive results not only on the opioid use-related outcomes, but also over associated symptoms, like depression.

As adjuvant agents, olanzapine may be efficient for aggressive behaviours in opioid dependent patients, memantine could improve cognitive function and decrease the inflammatory processes associated with substance use disorders, and dextromethorphan may also help decreasing the inflammatory processes. Further research is needed in order to verify the efficacy and tolerability of olanzapine, memantine and dextromethorphan as adjuvant agents.

Major radiological threats and emergencies requiring public health preparedness (the example of Greece)

Athanasios Zafeirakis[1], Ioannis Galatas[2]

Abstract: *Radiological emergencies carry the potential for major disruptions to public health care provision, due to their infrequency, unpredicted nature, delay in appearance of adverse effects and the grave psychological impact on sufferers and society. This study aims to describe and analyze the main categories of radiological hazards and emergencies that require hospital response and preparedness at a nation-wide level, taking into specific account the example of Greece. These radiological threats are either accidental, like reactor emergencies and accidents in hospital or industrial units implementing radiological sources of high activities, or deliberate, like detonation of nuclear devices and malicious use of various radionuclides.*

Keywords: *public health, radiological incidents, radiation emergencies, preparedness, nuclear terrorism*

INTRODUCTION

Even though natural disasters and biological hazards are currently the most frequent hazards for massive casualties, recent data suggest that radiological emergencies from various nuclear incidents may not be a reassuringly remote possibility. Till the year 2015, more than 420 radiation incidents of various degrees of severity have occurred, thus surging the global preparedness to a steady ascent [1], whilst specific deficits in training and experience may lead to devastating increase in the victims and mortality rate in the case of a major radiological event, either accidental or malicious. Furthermore, there are roughly ten million sealed sources of radionuclides used for peaceful applications worldwide; only between 1995 and 2008, more than 600 of them were either lost or stolen and less than the half were eventually retrieved [2].

COMMONEST TYPES OF RADIATION EMERGENCIES

Greece does not have a nuclear power industry; thus, Greek radiation preparedness is directed mainly to radiological scenarios of low probability, with rather minor health and social impact compared to major accidents from power reactors. However, a wide variety of radioactive sources is used in medicine, industry and research. Several types of severe radiological emergencies that would necessitate a special medical response are bellow analyzed in detail.

Nuclear detonation

The detonation of a nuclear weapon constitutes the most catastrophic radiological scenario; the enormous number of casualties from the shock-wave, the thermal burns and the ionizing radiation would probably lead the health network of any urban target in total collapse. Although the probability of a terrorist attack involving the detonation of a nuclear device is considered rather unlikely, the scenario of a single, low-yield nuclear weapon, stolen from a military facility, for a major attack in a densely populated modern metropolis, appears as a quite feasible and thinkable perspective of the 21st century's terrorism, according to US strategic analysts [3].

Reactor Emergencies

Following a reactor emergency, it is expected that a radiological contamination will occur to the surrounding environment and also external exposure and contamination through inhalation or ingestion may affect the general

athzafeirakis@gmail.com

public. Although many radionuclides are produced in a nuclear accident, the most important to human health are cesium-137 (Cs-137), strontium-90 (Sr-90) and iodine-131 (I-131) [4]. Apart from radioactivity, reactor emergencies may disperse long-lasting psychological consequences to enormously large populations [5].

The two most catastrophic reactor emergencies were the case of Chernobyl, Ukraine (April 1986), when enormous quantities of radioactive contaminants were dispersed across all continents [6], causing an extensive increase in neoplastic diseases and genetic malformations to the affected population [7], and that of Fukushima Daiichi, Japan (March 2011) which affected heavily the pacific ocean [8]. The size of the consequences of this kind of radiological incidents is vastly influenced by the meteorological conditions (mainly winds) prevailing in the area that would facilitate the movement of the contaminated cloud and deposits; in 1986 disaster, it took only ten days for the radio-contaminated cloud from Chernobyl nuclear power plant to cross southern Europe and arrive in Greece. Therefore, all nuclear power plants and radiological waste storage sites in Europe pose an existing threat. Yet, seismic activity is another factor that needs to be considered, especially concerning the seismogenic arc of the Asia Minor coast. Regarding the Balkan neighbors of Greece:

a. There are currently no active nuclear power plants in Greek territory and the low-power experimental reactor supervised by the Greek Institute of Nuclear & Radiological Sciences and Technology is under permanent non-operation state since 2001.

b. Bulgaria operates one of the oldest commercial nuclear reactors in Europe in Kozloduy since 1974 and according to the Belgium report [9] the vulnerability to failure and accidents of such units has steadily grown in the last years. In Germany, an accident in a poorly maintained nuclear facility out-borders is regarded the most probable major radiation incident [10]. Yet, as the effects of nuclear disasters have no borders, that old Bulgarian unit located only 260 km far from the northern borders of Greece, poses a significant radiological threat for all Balkan countries. The construction of a second nuclear unit in Belene was officially terminated in 2012 [11].

c. Romania operates a nuclear power plant in Cernavodae, located 325 km far from the northern borders of Greece (Figure 1), and in the indefinite future it plans to construct a second, larger unit probably in Transylvania.

d. Turkey's first nuclear power plant, at Akkuyu, commenced construction in April 2018. Although rather remote from the Hellenic inland, a severe radiological accident in Akkuyu will heavily affect Cyprus (Figure 2). Plans for two more power stations in Sinop (Northern Turkey, by the Black Sea) and İğneadain (in the European part of Turkey) have currently stuck, mainly due to economic reasons [12].

Nonetheless, since there are so many nuclear power plants, nuclear weapons and nuclear waste storage facilities within EU member states, advanced preparedness and countermeasures are necessary, under the threat of a European version of the 9/11 scenario, presumably in a more sophisticated implementation, e.g. a cyber-sabotage that would affect or interfere in the function of a nuclear plant (e.g. in the cooling or control sections).

Figure 1: Nuclear power plants neighboring to Greece; the green islets illustrate seismogenic locations during the period 1972-1997

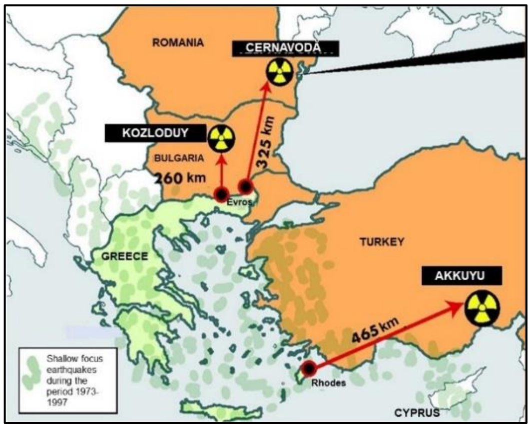

Figure 2: In the scenario of a severe radiological accident in the planned-to-operate nuclear power plant in Akkuyu, Cyprus would be inside the red zone of the disaster.

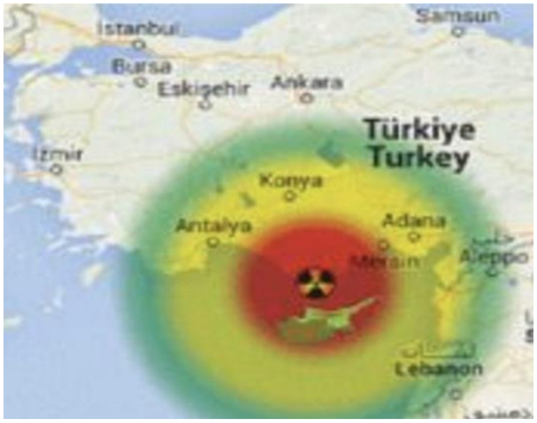

Accidental Medical overexposure

Medical teletherapy devices, though currently outdated by linear accelerators, are still used in many hospitals worldwide for cancer radiotherapy, by applying high energy gamma radiation focused on tumor targets. These devices typically use a single Co-60 source in a solid metal form, though a limited number of teletherapy devices use Cs-137 sources, which are in the form of a water soluble chloride salt, a much more dangerously prone to dispersion chemical form, thus making easier the contamination of people and environment [13]. The teletherapy device is securely encapsulated in heavy shielding and only highly trained personnel may operate it, because it poses extreme hazard if not properly handled. According to the decay energy and the physical half-life of the radionuclide, the equivalent dose for that radionuclide is 13 mSv per Ci per hour at 1 meter from the source; that may hypothetically lead a person to receive a lethal dose from a full 10,000 Ci unshielded Co-60 source when standing at one meter distance, within only a few minutes [14]. More realistic are of course scenarios of accidental medical overexposure from Co-60 teletherapy devices due to miscalculation of the radiotherapy treatment planning or improper function of such devices, or even when higher activities of radionuclides are accidentally administered in Nuclear Medicine departments. Although all above situations are considered as serious medical problems, they may not be classified as radiological incidents requiring hospital preparedness, because medical and radiation protection guidelines are regularly provided by health and physics specialists in each hospital.

Abandoned, lost or stolen radiation sources

Radiation sources may be improperly discarded, accidentally lost or even stolen for financial or malicious reasons. In many historical cases, decommissioned teletherapy units were unshielded, as a rule by people irrelevant to radiological education; the radioactive source was then stored or discarded and the metal shielding was scrapped. As a consequence of that, the perpetrators and sometimes the public, were either externally exposed to various levels of radiation or/and were heavily contaminated, resulting in serious injuries, illness or even death.

The worst of that kind of accidents occurred in 1987 in Goiânia, Brazil when an abandoned teletherapy source of a long-lived beta and gamma emitter, Cs-137 with activity of 1375 Ci, was unshielded by a group of metal scrapers. Four people received lethal doses of radiation, 28 suffered radiation injuries and 249 had been contaminated [15]. The delay in the verification of the radiological incident led to an uncontrolled and widespread radiological contamination in the urban district of Goiânia, including buildings, vehicles and soil [16].

Another potential radiological hazard comes from blood irradiators; these heavy-shielded devices contain Cs-137 with activity of 3,000-7,000 Ci [13] and are used in hospitals for the irradiation of blood prior to infusion. The most significant radiological incident concerning this type of device occurred in 2011 in a hospital in Finland where a blood irradiator containing 60.1 Tbq Cs-137 was exposed in high temperatures after a fire outbreak. Although no dangerous radioactivity was unleashed, quite a lot shortages in the flow of crisis information among the first responders, the radiation safety officer and the radiation safety authority were afterwards ascertained; furthermore defective preventive, storage and shielding protocols of such dangerous radiation sources were among the many lessons learned in the aftermath of a nearly disaster [17].

Incidents from dangerous industrial sources

Apart from medical sources, there are currently several hundreds of large industrial facilities worldwide that utilize high activities of ionizing radiation. The most dangerous of such industrial facilities is the gamma sterilization plant; such irradiation plants are usually located in industrial areas and are used to sterilize various products, most often food and medical devices, by using extremely high doses of ionizing radiation. A typical irradiation plant includes a large number of high activity Co-60 rod sources, housed in an array immersed in a water pool inside a shielded chamber.

The product to be irradiated is exposed by remote control to the sources for the time required to kill bacteria. Indicative of the high activities that are used in industrial irradiation is that a typical such facility contains from hundreds of thousands, up to some millions curies of Co-60 [13], that is roughly a thousand times more than the typical activity of a Co-60 medical teletherapy source.

Therefore, health emergencies occurring in industrial irradiation plants often lead to lethal levels of whole body absorbed doses after exposure of just some seconds [18]. Although such plants are highly secured and physically inviolable, operating according to globally standardized specifications and their safety to be established through decades of operational experience, training, supervision and safety systems technology, some sporadic serious accidents have taken place, like in Italy, 1975; Norway, 1982; [19]; El Salvador, 1989 [20]; Soreq, Israel, 1990 [19] and Nesvizh, Belarus, 1991 [18].

The thorough evaluation of all foreseeable hazards resulting from industrial facilities that use ionizing radiation needs to consider natural and anthropogenic disasters, failures in installation, operation procedures, supplies, machinery, technological infrastructures and safety education. Importantly also, users of radioactive material with longer experience possessed a surprisingly lower degree of nuclear security awareness compared to less experienced ones [21].

Malicious use of radioactive materials

Nowadays, it is widely accepted that international terrorism may have acquired the resources and technical capabilities to obtain or manufacture improvised nuclear devices or other types of radiological dispersal devices coupling conventional explosives and radioactive material [22]. The latter are known as "dirty bombs" and are much easier to be prepared than a nuclear detonation device and yet the raw materials can be found in industry, hospitals or research institutes. The appropriateness of a radiological source for malevolent applications depends on various factors like the size, accessibility and ease of portability of the source, the total radioactivity and physical half-life of the radionuclide it contains, the type of the radiation emitted (for example gamma emitters are suitable for external exposure, whilst alpha emitters only for radiological contamination) and also the physical and chemical form of the radioactive material [5]. For practical reasons the radioactive sources suitable for nuclear terrorism are classified into two general categories:

a. *Radiation exposure devices (RED)*; these usually involve small-sized sources with radioactive material emitting gamma radiation. In RED, the primary radiation source(s) is/are in a relatively intact physical state and shape, thus the radiological threat comes rather from external radiation exposure and usually raises minimal or no aspects of disseminated contamination. When in large quantity, like for example in the case of an unshielded medical teletherapy Co-60 source, the RED raises hazards of acute or chronic radiation syndromes to the victims. When of small quantity, the exposure dose to individuals is expected to be too low to allow for acute effects; however, the psychosocial fear of future cancers raises concerns of diffuse or uncontrolled public anxiety.

b. *Radiation dispersal devices (RDD)*; these involve larger quantity of radioactive material which is dispersed in micro-granular, airborne or water soluble form (as is usually the case for the radio-cesium chloride salt) over large areas, often by the use of conventional explosives, coupled with the radioactive substance. In this way, the contamination risk, either external (at the environment, skin, or cloths), or internal (by ingestion or inhalation) usually overwhelms the exposure threat. Furthermore, RDD carry the potential to cause complicated injuries, like blast and burn traumas from a chemical explosion combined with radiological contamination. And again, the psychological impact of such an attack, especially when affecting a large urban area, might provoke extensive economic and social disruption to a whole country.

Various radionuclides require enhanced nuclear security measures, since even gram or milligram quantities of some, assuming perfectly dispersed, might be enough to contaminate large areas above acceptable levels for habitation. The number of affected people in such a scenario also varies, according to the type of the bomb, the quantity of the nuclear material, the time and location of the attack. According to a scenario of U.S. Homeland Security Council [23], the concurrent blast of Cs-137 "dirty bombs" at three different locations in a densely populated urban area might cause 180 fatalities, 270 injured and 20,000 contaminated people at each site; hundreds of radiation induced cancers would also occur in the future unless tens of thousands people were relocated from the city [10]. The most common radionuclides that might be used in a RDD with corresponding thresholds to contaminate 1 square km are presented in Table 1.

Table 1: Common radionuclides that might be used in a RDD

Radionuclide	Threshold (grams) to contaminate 1 square km*
Co-60	0.01
Ir-192	0.01
Sr-90	0.37
Cs-137	0.48
Ra-226	13
Am-241	22.7
Pu-239	220

** refers to the theoretical amount of radionuclides in pure and perfectly dispersed form required to contaminate that area to the level that a person living there for one year would receive a cumulative dose of 20 mSv*

Concerning Po-210, there is always the threat of targeted assassinations like the case of Alexander Litvinenko, the first recorded victim of Po-210 radiation poisoning [24]; much scarier though is the theoretical scenario of a massive food poisoning, e.g. in grand hospitals, congress venues, cruise ships, etc. with lethal or pathogenic doses of radionuclides. Radio-contamination of the water is a far remoter perspective, due to both the sophisticated control mechanisms in central water supply reservoirs of the modern Metropolises and the vast quantities of radiological factors required to cause significant contamination of the water reservoirs. However, that is not always the case in smaller tanks irrigating small communities or sensitive infrastructures (e.g. hospitals) In any case crisis communication will play a significant role in dealing with such incidents, which may well overwhelm the health capacity and capability of the whole national medical network.

Furthermore, the enormous financial disaster that would result from a long-lasting radiological contamination of critical infrastructures, such as ports, train stations, government buildings, central squares, etc, and the economical loss of the consequent shutdown after such an incident for a large city has been estimated to tens of billions U.S. dollars [25]. Table 2 illustrates the theoretical probabilities for deterministic effects (acute or chronic radiation syndromes), concerning the threats described above whilst Table 3 presents the medical and public health characteristics of the three major categories of radiological events.

Table 2: Theoretical probabilities for deterministic effects (acute or chronic radiation syndromes), for radiation exposure and for radiological contamination

		Theoretical probability	Source of radiation	Acute radiation syndrome	Chronic radiation syndrome	Radiation exposure	Contamination	
							External	Internal

Nuclear weapon	+++	+++	+++	+++
RED	+	++	+++	+++
RDD	+	+	++	+++

+++/++/+: *high/intermediate/low probability; RED: Radiation Exposure Device, RDD: Radiation Dispersal Device*

Contamination of food and water

The radiological contamination of food and water or any other goods of public consumption is another health emergency radiation scenario. That could result by two main reasons:

a. As a consequence of an accidental radiological accident, e.g. from a reactor emergency, that might release radiological contaminants to the environment and then to the food chain, or from a damaged radiological source, which might then be dispersed and contaminate the surrounding area. In the reactor emergency scenario it is expected a widespread contamination, leading to low level absorbed doses to a large population. Yet there is usually expected to be time for precautionary measures for the public protection, whilst as regards accidents involving radiological sources, these occasionally may be latent for a longer period of time [16].

b. As a malevolent act; that is the intentional contamination of public supplies with radioactive materials, or the attempt to assassinate specific individuals. In the case of a massive deliberate contamination of consumable public supplies, it is expected that the public would receive a rather low dose of radiation per person due to the dilution of the radioactivity load into a large pool of mass or consumed volume and consequently, due to the extremely large amounts of radioactive material required to achieve high levels of large-scale contamination. However, targeted assassinations [24] are another gloomy perspective of radiological terrorism; high doses of extremely dangerous radionuclides (Po-210, in that case), incorporated in the human body can cause genuine lethal deterministic radiation effects.

In any such case, fast actions from the public authorities involving radiological experts and the media are mandatory to quickly assess the health impact and reduce the consequences. Concerning the level of radionuclides in water supplies, the World Health Organization (WHO) has developed detailed guidelines [26]. On the social level however, an uncontrollable public concern or even panic is to be expected in such cases, as past experience has shown [27]. Furthermore, massive national or international financial consequences are expected concerning the distribution chain of food merchandise.

CONCLUSIONS

The key point concerning all above described cases of radiological emergencies, is that appropriate assessment of potential public threats and required preparedness or response actions should be applied before the appearance of the consequences of such incidents. Thus, continuous awareness and preparedness for such hazards is crucial for all public health stakeholders.

Management of hepatitis C virus (HCV) infection: an update

Ion Ștefan[1,2], Constantin Ștefani[1,3], Carmen A. Sirbu[1,3], Any Docu-Axelerad[2], Florentina Ioniță-Radu[1,3]

Abstract: *Million people worldwide are affected by the hepatitis C virus (HCV). The highest incidence of illness was between 1945 and 1975. It was also estimated that 70% of those people were not tested for the disease. Most recent treatment concepts are safe, highly effective and have a vital public health influence by achieving a viral constant response in a significant proportion of treated patients. It helps reduce liver fibrosis, liver cancer risk and dissemination. With its increased population incidence, HCV becomes a serious public health problem. This review discusses the current literature in this field in terms of the importance of screening of HCV, follow-up, treatment and includes considerations in specific populations such as patients with cirrhosis, with HIV/HCV co-infection, patients with HBV/HCV co-infection and with renal damage.*

Keywords: *hepatitis C virus, Direct-acting antiviral therapy, co-infection*

INTRODUCTION

The primary cause of final-stage liver disease in the Western world is the Hepatitis C virus (HCV). Notably, HCV is the only chronic viral infection in humans that can be healed [1,2]. The consequences of chronic infection (HCV) include cirrhosis (compensated and decompensated), portal hypertension, hepatocellular carcinoma and eventually liver-related death.

Fibrosis progression may vary due to multiple factors such as age, hepatitis B, alcohol consumption or human immunodeficiency virus (HIV) co-infection [2].

After cirrhosis is established, a yearly incidence of hepatic decompensation such as jaundice, episodes of ascites, variceal bleeding and encephalopathy of 3.9-5.7% and a yearly incidence of hepatocellular carcinoma of 1.4-3.4% has been reported [2,3].

The percentage of seropositive antibodies to HCV increased from 2,3 to 2,8 % between 1990 and 2005 [3] and the disease complications are increasing due to the ageing population and the percentage of liver fibrosis, which in time leads to hepatic insufficiency risk [4].

The key to the long-term benefits in HCV infection is to arrive at constant serologic feedback which is the lack of viremia 12 weeks after the end of the therapy [5].

This sustained viral response (SVR) decreases the prevalence of hepatocellular carcinoma, morbidity related to the risk of hepatic insufficiency and mortality of infected individuals [6-8].

HCV INITIAL TESTING AND FOLLOW-UP

Diagnosis of chronic C virus infection is done by testing anti-HCV antibodies. HCV RNA polymerase chain reaction is only required if the anti-HCV is positive and it confirms the diagnosis of chronic C virus infection [9,10].

There is a group of people (about 15-30%) who have a positive anti-HCV test and negative RNA HCV polymerase chain reaction [11] test. Those are people who can naturally clear out the infection. Spontaneous removal of the C virus is particularly rare after 6 months in which the person has acquired chronic infection [11].

People born during 1945-1975 [12,13], should perform

screening for Hepatitis C annually. From 2020 universal HCV screening is recommended for all adults aged 18.

Annual HCV testing is required for all individuals injecting drugs, pregnant women, people with an immunodeficiency [14], persons with various pathologies, individuals with ongoing risk behaviours or exposures and persons who have unprotected intercourse with men [15,16] according to the American Centers for Disease Control and Prevention (CDC) and the American liver disease Survey Association (AASLD).

People with known or suspicious cirrhosis have an increased risk of liver complications and need to be frequently followed. Individuals who are immunodepressive (e.g.: chronic hemodialysis) [17] or who may have been exposed to HCV in the last 6 months and have not developed antibodies should be tested for HCV RNA even if they have had negative anti-HCV testing.

CLINICAL CARE FOR PERSONS WITH ACTIVE HCV INFECTION

Once diagnosed with active HCV infection, patients need counselling and specific clinical assistance before the initiation of antiviral therapy.

The most important thing is the prevention of further liver damage [18]. First of all, counselling patients and sustaining them not to consume alcohol, because there is a tight connexion between alcohol use, progressive fibrosis and the development of hepatocellular carcinoma (HCC) [19,20]. Moreover, people have to be trained on how to prevent the transmission of this infection.

This training can greatly reduce the hepatitis C rate. Some of the rules are: to avoid the sharing of different tools (toothbrushes or razor blades) and to avoid the possibility of others coming into contact with the blood of an infected person [18-20].

Assessment of hepatic fibrosis, hepatitis B virus [20], immunodeficiency and existing pathologies is required to determine the treatment strategy for HCV infection.

Every person with HCV should get vaccinated against hepatitis A and B and for persons with cirrhosis, vaccination against pneumococcal infection is recommended.

DIRECT-ACTING ANTIVIRAL (DAA) THERAPY

The physical exam conducted on the liver, routine blood tests (e.g. complete hemogram, alanine aminotransferase (ALT) and aspartate aminotransferase (AST), albumin, bilirubin), elastography indicating cirrhosis (Fibroscan), liver imaging (ultrasound or CT), can indicate the severity of liver damage and aid for a previous assessment of the treatment scheme to follow for hepatitis C infection [21].

Recommended pretreatment laboratory tests are pursued to confirm chronic HCV infection and to rule out decompensated liver disease, HBV, HIV co-infection and renal disease, and/or current pregnancy previous therapy initiation, considering that they need more subtle care [22].

During antiviral therapy, it is recommended to inform patients about potential drug-drug interactions and to monitor adverse events. It is important to schedule some clinic visits or to have telephone contact to check medication compliance [23].

Patients suffering from diabetes can have a hypoglycaemia drop and blood glucose monitoring is recommended.

Patients undergoing anticoagulant treatment (warfarin) should be carefully monitored because they may experience changes in the anticoagulation status [24,25].

Clinical trials have proved the safety [26] of strong therapeutic success of Glecaprevir (300mg)/Pibrentasvir (120 mg) [27] taken for 8 weeks and Sofosbuvir (400mg)/ Velpatasvir (100mg) [28] for 12 weeks for treatment persons without cirrhosis no matter of HCV genotype.

To evaluate therapy response, HCV RNA and hepatic aminotransferase testing is counselled 12 or more weeks after finishing DAA treatment. Undetectable HCV RNA represents virologic cure and sustained response to treatment.

Numerous benefits for the health and general condition of the patient, including improved AST levels and reduced inflammation with decreased progressivity of liver fibrosis [29].

Patients healed by HCV, those with a sustained viral response (SVR), show a decrease of up to 70% of the risk of HCC development [30,31]. In the absence of cirrhosis, individuals with SVR do not demand liver-specific monitoring, but for those with constant HCV risk factors or an increase of hepatic aminotransferase, counselling and HCV RNA testing once a year is recommended [32].

Between 1% and 7% is the annual rate of hepatocellular carcinoma in patients with HCV cirrhosis, and for this reason, is recommended an ultrasound exam and periodic upper endoscopic monitoring.

The most frequent HCV genotype from all 7 genotypes is Genotype-1 [33]. In Europe and Central America Genotype-1, b is the most common HCV subtype [33].

Patients should be handled by clinicians with expertise in managing HCV therapy failure. Persons with persistent elevated hepatic aminotransferase levels and achieved SVR demand reevaluation for other causes of liver damage [34,35].

Assessment for liver damage progression every 6-12 months is counselled for patients with no treatment response. Ultrasound monitoring for HCC and alpha-fetoprotein [36] every 6 months is recommended for persons with cirrhosis. AASLD guidance on portal hypertensive bleeding in cirrhosis recommends upper endoscopic monitoring for oesophageal varices [37].

HCV AND COMORBIDITIES

Liver lesions can progress faster in the case of HCV-HIV coinfection [38,39]. Careful evaluation and observation of potential interactions between medicines are required.

Guidelines recommended the same therapy in the treatment of HCV mono-infection and HCV-HIV co-infection [39]. For patients with genotype 1a and 1b, with no cirrhosis, therapy for patients with mono HCV infection is with ledipasvir/sofosbuvir for 8 weeks, and 12 weeks in patients with co-infection [40].

For genotype 1a, 1b, 2, 3 and 4 individuals with compensated cirrhosis, AASLD-IDSA HCV proposes glecaprevir/ pibrentasvir for 8 weeks in persons with HCV and 4 weeks more in patients with co-infection [40]. And for genotypes 5 and 6, with or without compensated cirrhosis, glecaprevir-pibrentasvir for 8 weeks in patients with HCV infection and with 4 weeks more for those with co-infection, is recommended [40].

The particular examination should be given by controlling and managing HIV antiretroviral and HCV DAA drug interaction.

Measurements of serum creatinine and creatinine clearance are included in the patient assessment with HCV before treatment, and the stage of renal disease may be determined based on these values.

The normal value of GFR is 130 and 120 mL/min/1.73 m^2, and kidney failure is defined by a GFR less than 15mL/min/1.73 m^2. HCV is associated with the rapid development of kidney damage and renal carcinoma [41]. Hemodialysis is considered to be a risk factor for acquiring HCV infection [42].

The selection of DAAs should be carefully considered and based on patient characteristics, concurrent drugs and HCV genotype [43]. For all six major HCV genotypes, glecaprevir-pibrentasvir have shown to be effective and safe in persons with kidney chronic disease and HCV infection.

Sofosbuvir-based therapy does not have the safety and efficacy data to support its use in patients with chronic kidney disease [44].

Co-infection HBV-HCV has an approximate worldwide incidence of 1-15% [45]. In some cases of co-infection, there may be various effects on the progression of the disease, clinical manifestations and patient supervision, so the liver profile should be observed together with the level of transaminases [46,47].

The anti-viral activity against VHB and HCV is the Peg IFN-based regime. Its efficiency increases when combined with ribavirin: 35% efficiency in HBV and 50–60% efficiency in HCV. This combined therapy with ribavirin reduces the risk of HCC development by 34% [48,49].

In patients with chronic kidney disease and chronic C-virus infection, the DAA treatment works well, the sustained rate of virological response is substantially increasing [50-51].

CONCLUSIONS

The rate of viral eradication and the increase in the tolerance of adverse reactions have been sustained by the emergence of DAA agents, which have counted heavily in the treatment of patients with HCV, co-infections with HBV, HIV and CKD. Interrelations between drugs should be carefully checked before delivery of antiviral therapy.

The anamnesis should contain questions about the medical history of the patient (surgical interventions, diabetes, infections), other factors that may accelerate chronic HCV infection (alcohol, obesity), transmission risks and the approximate duration of infection, signs and symptoms of disease or other extrahepatic manifestations.

The treatments aim to achieve a sustained viral response and to keep disease manifestations under control. For each genotype of HCV, there are multiple therapies approved with quite high effectiveness.

Management of infectious complications in diabetes mellitus mellitus patients

Razvan Hainaroșie[1,2], Viorel Zainea[1,2], Andreea Rusescu[1], Ruxandra O. Iana[1], Teodora Ghindea[5], Adrian P. Suceveanu[4], Dragos C. Ștefanescu[1], Irina G. Ionita[1], Cătălina Pietroșanu[1], Anca Pantea Stoian[1]

Abstract: *Diabetes mellitus is a serious condition, causing multiple health problems due to the disease itself, but also to the complications that these patients are predisposed to. Being a current health problem, many patients tend to disregard the doctor's recommendations concerning the necessary measures to maintain adequate and continuous control of the glycaemia levels. This, in turn, may cause complications, which include neuropathy, microangiopathy and a predisposition to infections due to weak local defence mechanisms.*

In otorhinolaryngology, the infectious pathology is one of the most often causes for presentation to the physician. Ranging from common otitis, acute pharyngitis or laryngitis and sinusitis, these different entities will cause significant discomfort for the patient, prompting the need for medical care. In patients with diabetes, the natural course of the disease is altered, with more severe symptoms, a more extended period of recovery and the predisposition for aggravated cases with the tendency to complications. Such complications may be life-threatening if we take into account the complications associated with acute sinusitis for example, which include orbital or cerebral abscesses.

Our paper aims to present the authors experience on the complete approach of patients with infectious pathology concerning the sinuses associating diabetes mellitus.

Always, we must keep in mind that patients with diabetes represent a particular class of patients that require a personalized approach. They are predisposed to a vicious circle, in which the infection causes diabetes imbalance, which in turn decreases the defense mechanism and predisposes to complications. The correct management must always include a proper control of diabetes, a complete evaluation that will determine if complications are already present and aggressive management of the infection, with regular check-ups to determine the evolution of the patient.

INTRODUCTION

Due to the high prevalence of diabetes mellitus in the general population, this group of patients has always benefited from practical guides concerning the proper management of the disease and the therapy protocol in case of imbalances or complications of the disease. The same principle applies for the complete approach of any secondary problems, such as electrolites imbalances in the normal body functions or associated infections [1, 2].

Corresponding author: Catalina Pietrosanu
catapietrosanu@gmail.com

It is accepted that patients with diabetes are predisposed to infectious complications due to the depressed local defense mechanisms, the body's incapacity to limit the infection and the high risk of unbalanced glycaemia levels [3-5]. However, studies that show the specific cellular dysfunctions that cause this problem are still limited. Some even stated that the link between diabetes and infections is difficult to establish [6], while other studies reinforce this concept [7]. However, the number of patients included remains limited and the conclusions scarce.

One fact remains unanimously accepted, and that is that the management of a patient with diabetes that associates an active infection is different and must be more thorough than that of a non-diabetic patient with the same illness. The guides clearly state that the infection must be limited, while the diabetes is kept under control with normal glycaemia levels, even if the use of insulin becomes necessary. In this manner we can avoid further complications that can prove to be life-threatening.

The mechanisms by which diabetes mellitus affects the normal immune capacity of the body are still unclear. Studies so far have demonstrated an association between the presence of diabetes mellitus and a decreased function of polymorphonuclear cells and macrophages [8, 9]. These cells involved in the natural processes of chemotaxis and phagocytosis present with a decreased response, thus lowering the host’s capacity of self-defence. This was demonstrated when comparing the function of these cells in patients with diabetes compared to non-diabetic subjects [10].

Another mechanism that was described in order to explain the predisposition to infectious complications of diabetic patients is represented by disturbances in the humoral immunity, such as a low response of cytokines following stimulation or low levels of complement factor 4 [11].

In order to provide accurate and efficient management of these patients, it is essential to establish which mechanisms play the most significant role. Studies so far suggest that humoral adaptative immunity remains efficient also in patients with diabetes mellitus, as proven by their capacity to respond well to vaccines [12, 13]. As far as the cellular immunity is concerned, dysfunctions at this level have already been demonstrated, although at a lower level than in cases of HIV infections or other immunosuppressant conditions. Of this, one of the most important aspects is represented by lymphocytes dysfunctions in diabetes patients and delayed hypersensitivity reactions [14].

Diabetes mellitus may influence the onset and evolution of infectious diseases by other means as well. High levels of blood glucose create an environment in which a microorganism is more virulent and presents an increased adherence to the cells. This is especially true in patients with long-term unbalanced diabetes that present constant high levels of blood glucose.

Another problem that may occur in patients with diabetes and infections is the risk of diabetic ketoacidosis [3]. This complication may prove to be fatal in a large number of patients when it occurs, and it requires intensive care and aggressive management [15].

Due to all these factors, the management of the diabetic patient with an infection must be a multidisciplinary one. The team must include diabetes and nutrition specialist, an infectious diseases specialist, an intensive care unit doctor if the condition of the patients requires it, and specialist that treats the affected organ. Only with such a complex approach can these patients be balanced and healed in safe conditions.

Infections in diabetic patients can appear at any level and can involve primarily any organ. Starting from common cutaneous infections and up to severe ones, such as meningitis or myocarditis, these infections can appear alone or as part of a more severe condition and can lead to sepsis. The source of the primarly infection must be identified, and proper care measures must be ensured as soon as possible. These include broad-spectrum antibiotics as a first measure, followed by an antibiotic treatment according to an antibiogram after samples have been sent for testing. Other measures include anti-inflammatory drugs and the surgical drainage of any collection

MATERIALS AND METHODS

This paper aims to describe the proper management protocol used in our clinic for diabetic patients presenting with infections in the ENT field, more precisely the management of rhinosinusitis in diabetic patients.

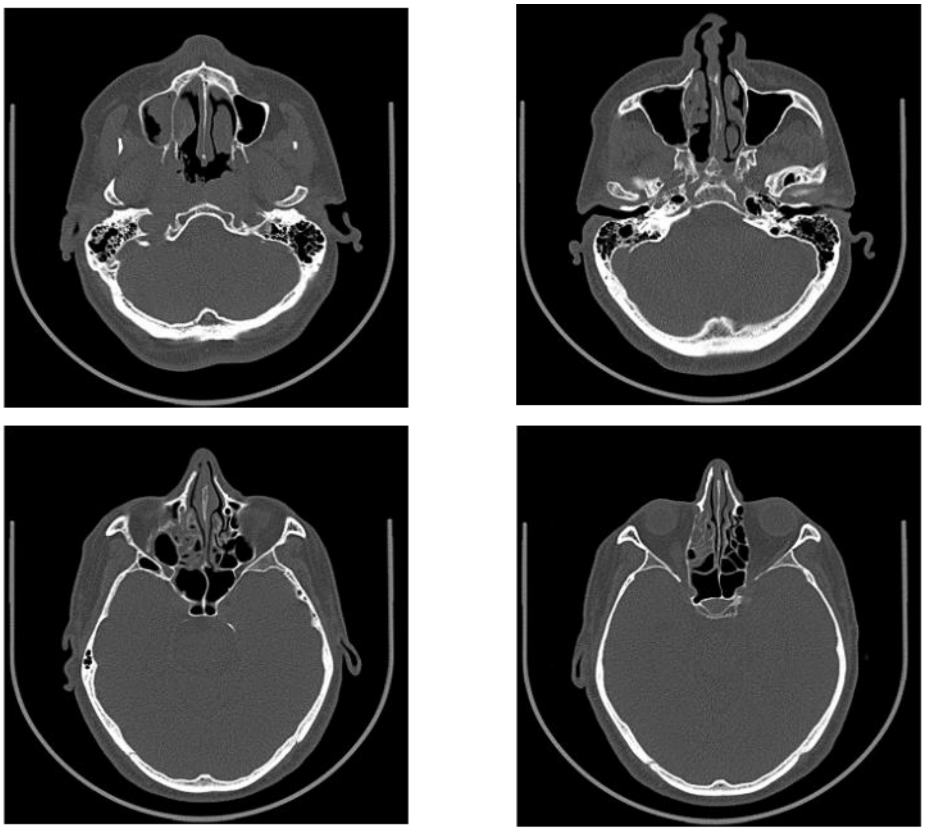
Taking into account the septic state of ENT cavities, we must keep in mind that patients with diabetes are more predisposed than the general population to develop infectious conditions. These may include otic infections, laryngeal of pharyngeal problems, but one of the most common conditions is represented by sinusitis.

Patients diagnosed with sinusitis usually associate one or more of the following complaints: purulent nasal discharge, headache, cranio-facial pressure and vertigo. In acute cases, high fever may occur. The causes of sinusitis are divided into nasal and odontogenic. The last one may represent a severe complication in patients with diabetes due to their predisposition for dental problems.

In such patients, the primary protocol is similar to that of non-diabetic patients. Antibiotic treatment associated with anti-inflammatory drugs, antihistaminics and proper hydration are the most common measures and must always associate nasal decongestants.

Complete blood work must be performed in order to asses the toll this episode inflicts on the organism. Efficient monitoring of the patient is mandatory, especially in diabetic patients, due to the risk of rapid-onset complications.

Figure 1: CT images of a patient with diabetes and sinonasal mucormycosis.



The complete diagnosis of these patients should include a computed tomography, which reveals the specific extension of any sinusitis. This is not routinely performed in the acute period, except for the cases that raise the suspicion of complications, such as an orbital abscess or meningitis. If the patients associate a positive response to therapy, the imagistic examination should be performed at a period of time following the acute infectious episode.

Taking into account the agent that causes the infection, sinusitis can be either bacterial or fungal. Each can occur at diabetic patients, but they are at risk of developing a more significant number of fungal infections than the general population. This may be caused by both low local defense mechanisms, but also to the high incidence of dental problems in these patients.

Figure 2: Mucormycosis lesion of the mucosa of the rhinopharynx in a diabetic patient – intraoperative view.

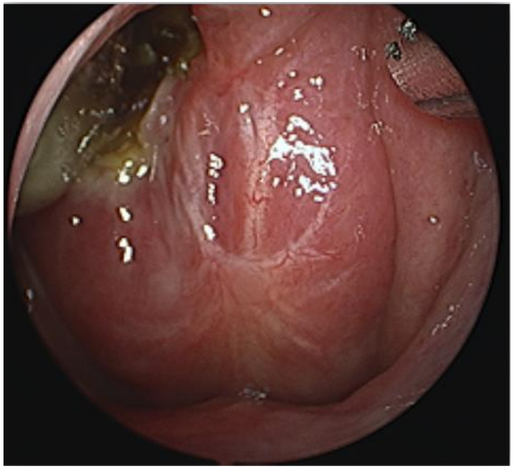


Figure 3: Intraoperative view of the same patient following an extensive debridation up to healthy tissue.

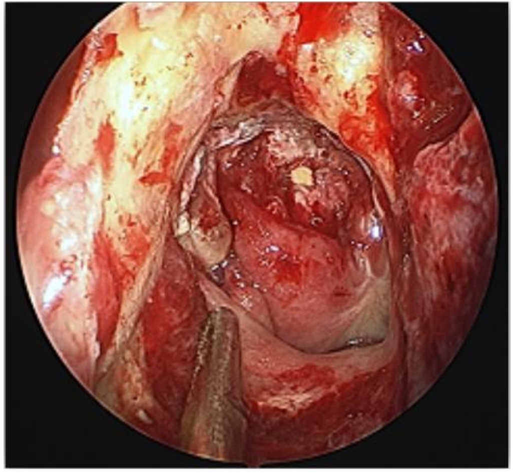

A significant aspect of the management of patients with sinusitis is the necessity to drain any purulent collection that prevents complete healing. The principle must be applied for all patients, but in diabetic patients, it is extremely important. Oral medication is more often inadequate in completely controlling the course of the disease. The surgical drainage may prove to be one of the simplest gestures that can be performed, with low risks. This principle applies to all patients but can be the only viable option in particular cases, such as Mucormycosis infections. In such cases, the surgical debridation of the affected area up to healthy tissue may be the only way to control the spread of the fungi.

The need for a multidisciplinary team remains, especially in patients with unbalanced diabetes that may require an aggressive approach [16]. Without adequate control of glycaemia levels, the healing process will be longer and less efficient. Also, an acute infection associates the risk of fluctuant glycaemia levels, with secondary complications. These patients have a higher risk of sepsis due to the decreased power of the body to contain the infection.

The surgical approach must be thorough and ensure adequate drainage of the infected sinuses. The same principle applies to bacterial or fungal sinusitis. Only the complete removal of the infectious reservoir will allow for a complete recovery.

RESULTS AND DISCUSSIONS

Patients with diabetes, especially if poorly controlled, represent a surgical challenge. Although the intervention itself follows the same principles as in non-diabetic patients, the surgeon must be even more thorough during the intervention and ensure that all infected sinuses have been drained and, in cases of fungal sinusitis, all affected tissue has been removed. The weak local defense mechanisms are not reliable in such cases, and any infectious reservoir remaining can cause a relapse in the disease [17].

These patients represent a challenge from the point of view of the anesthetist as well [18, 19]. The glycaemia levels are more difficult to control during the infectious process, they associate a higher risk of complications, including sepsis, and the response to usual therapy may be altered.

In our experience, the surgical gesture of draining the infected sinuses can be salvatory. Antibiotic or antifungal treatment is mandatory, depending on the type of sinusitis. However, therapy alone can be insufficient and unable to limit the infection. This is even truer in diabetes patients, due to their body's low defense mechanisms. In cases of sinusitis, after a complete diagnosis that must in some cases include an imagistic evaluation, the surgical intervention is advisable if the response to treatment in the first days is insufficient or if any complications appear. The imagistic examination of choice is represented by a CT scan, which can be completed with an MRI if complications, such as orbital or cerebral extension, are suspected.

The functional endoscopic sinus surgery is a minimally invasive one and ensures a good visualization of the affected area. It allows the surgeon to control the patency of every sinus and verify if all sources of infection have been removed.

The postoperative care is crucial, being a key element in the complete recovery of the patient. Especially in a diabetic patient, maintaining appropriate glycaemia levels in the postoperative period will increase the patient's chances of a full and uneventful recovery.

CONCLUSIONS

Diabetes remains a challenging disease, despite the advancements that are continuously made concerning the therapy. The diabetic patient remains a particular one, requiring a more thorough approach, especially when an infectious process is present. People with diabetes are at higher risk to develop complications and more susceptible to inadequate and incomplete healing. Another frequent problem is caused by the multiple problems caused by diabetes, even concerning the local defense mechanisms. In such patients, a vicious circle may occur, based on the relationship between infection and unbalanced diabetes, where diabetes favors the infection. This, in turn, causes difficulties in maintaining normal glycaemia levels, which paves the way for infectious complications.

The authors recommend a multidisciplinary approach of patients with ENT infections and diabetes. This applies even more for patients with sinusitis, which is a common disease but can develop even life-threatening complications if incompletely treated. If the disease does not respond well to medical therapy, it is advisable to ensure the surgical drainage of the affected sinuses and the ENT surgeon must do so before complications. For patients with diabetes, we must also bear in mind that the onset of complications may be more rapid and dramatic.

Once the infection has been drained, the healing process will have a normal course only if the patient is well balanced, with normal glycaemia levels. Insulin may be necessary, even in patients that did not require this prior to the event. Only the proper management of diabetes allows a normal recovery. Even so, these patients must be carefully observed to ensure no secondary complications or relapses occur, and if such cases occur, the necessary measures must be quickly taken, including revision surgery if needed.

Management of war-related vascular injuries: A civilian surgeon experience in the treatment of war casualties at a secondary care hospital

Bariş Akça[1]

Abstract: *Background: This study presents the management of patients with war-related injuries and early results of vascular injuries treated at a secondary care hospital neighboring to civil war.*

Methods: Between December 2013-December 2014 ninety-six war-related injury patients evaluated by a single vascular surgeon and participating disciplines according to components of injury in polytrauma patients. Thirty-six patients who underwent vascular surgery were retrospectively registered to the study. Demographics, treatment and early results of patients reviewed.

Results: Mean age was 26.69±11.80 (7-66) years and 91.66% (33/36) were males. Injuries were caused by shrapnel wound due to bombing 61.11% (22/36), stab wound 8.33% (3/36), gunshot wound 30.55 % (11/36). The number of patients with polytrauma was 29, seven patients had isolated vascular injury. Among 42 arterial and 31 venous injuries primary suture repair, autologous vein graft interposition and prosthetic graft interposition performed to 20.54% (15), 28.76% (21), 19.17% (14) respectively. Amputation and all-cause mortality were %8.3 (3/36), 13.8% (5/36) respectively.

Conclusions: Vascular injury with concomitant trauma is the main issue of war-related injuries. Surgeons should be cautious about patients who were initially deemed not to need surgery for vascular injury and then were found to need it. Repetitive physical examination is very important in case of any suspicion, especially in limited conditions for diagnostic tools like CT angiography. A rapid, careful multidisciplinary evaluation of experienced surgeons for the diagnosis and the treatment priorities in war-related injury patients may lead to increase life and limb salvage rates with a better quality of life.

Keywords: *vascular system injuries, war-related injuries, mortality, amputation, multiple trauma*

INTRODUCTION

Vascular injuries reported as varying rates of 2-3% of civilian trauma [1, 2], while about 7% of war-related trauma [3]. War-related vascular injuries frequently result in life-threatening hemorrhage or limb loss, and while the amputation rate was 60 % in the past, with ligation being the preferred technique for arterial injuries, today this rate has decreased to as low as 1 % through developments in early transport, damage control methods providing hemodynamic stability, diagnosis and complex treatment techniques [4, 5]. Early intervention is considered crucial for a successful outcome, although the management of vascular injuries is clinically challenging even for experienced surgeons when resources are limited, particularly in polytrauma patients, as imaging methods like computed tomography angiography (CTA) or angiography is necessary for prompt diagnosis, as well as for prompt and appropriate treatment. Ideally, war-related injuries should be treated by surgeons with military surgery experience, although civilian surgeons may find themselves in practicing military surgery without prior

training or experience in this field [6].

As a result of ongoing civil war in Syria, an increasing number of patients with war-related polytrauma have been managed in a frontier secondary care hospital which neighboring the civil war, in Kilis, Turkey. This study presents the experiences of a single civilian surgeon with war-related injury management strategies and the early results of vascular injuries treated at a secondary care center with limited resources.

METHODS

Between December 2013 and December 2014, 96 patients with war-related injuries were evaluated for suspected vascular injury through a multidisciplinary approach involving a single vascular surgeon and other disciplines, who were involved depending on the components (cranial, chest, abdomen, bone fracture and soft tissue loss) of injury in polytrauma patients. Data of patients were recorded for retrospective analysis in real time. This retrospective study was conducted after obtaining the Ethical Committee approvals of Inonu University and where the work was carried out.

All patients were transferred to our hospital from the place where the injury occurred. In accordance with Advanced Trauma Life Support protocols and damage control principles [7, 8], tourniquets were routinely applied to all patients to achieve rapid hemorrhage control, and permissive hypotension (massive red blood cell, plasma, and minimal crystalloid infusion) was used to initiate a hemostatic resuscitation plan aimed at correcting metabolic imbalances. Subsequently, patients were evaluated for vascular and other injuries. In the absence of angiography and CTA, diagnosis of vascular injury was made almost entirely through physical examination findings, with a Doppler ultrasound (DUS) used when possible. If a patient presented with only hard signs of vascular injury, such as active pulsatile hemorrhage, absent distal arterial pulse, ischemia, expanding or pulsatile hematoma with no concomitant injury, immediately transported to the operating theater for vascular repair. After the multidisciplinary agreement about the benefit of vascular repair and concomitant surgical interventions, and an initial surgery decision according to clinical status at admission, patients with polytrauma were sent immediately to the operating theater. However, patients presenting with soft signs of vascular injury (non-pulsatile and non-expanding hematoma, palpable but diminished or unequal distal arterial pulses, bone fracture, peripheral nerve deficit and history of bleeding that subsided spontaneously) and with no immediate threat to life or limb, were preferred to be referred to a center where further investigations could be made. If there was no such opportunity, these patients were evaluated by DUS, if possible, or mostly through repetitive physical examinations, for clinical findings of ischemia, cyanosis, the absence of arterial pulse and hemorrhage. CTA or angiography was essential for diagnosis and the treatment options in 19 (19.79 %) polytrauma patients with uncertain physical examination findings, hence they referred to the relevant centers.

Among 96 patients evaluated for vascular injury, a total of 36 (37.5%) patients operated by vascular surgeon enrolled in the study. All patients received a tetanus vaccine and dual antibiotics prior to surgery. The initial surgical exploration was usually performed by the vascular surgeon, both for better bleeding control and arterial and venous repair, especially in injuries of the extremities, based on hemodynamic status and duration of ischemia. The exploration of injured vessels was performed via standard incisions if in the same course as the injury area; otherwise, proximal and distal control of the vessels was obtained directly from the injury area. In patients with extremity injuries (bone, nerve, and soft tissue damage, whether individually or together) vascular repair was performed immediately after proximal and distal control of the vessels to achieve better bleeding control and stable hemodynamic status in cases where extremity-threatening critical ischemia existed. Otherwise, vascular repairs were made after bone stabilization with external fixators.

Systemic Standard heparin was used intra-operatively, based on the level of bone and soft tissue damage/loss in non-coagulopathic patients. Thrombectomy was performed routinely with an embolectomy catheter after the routine assessment of proximal inflow and distal backflow. Also, the distal segment of the artery was cleansed with heparinized saline in patients for whom systemic standard heparin could not be used.

Vascular injuries were managed via simple repairs, end-to-end anastomoses, interpositions of the autologous saphenous vein graft or polytetrafluoroethylene (PTFE) graft and simple ligation methods. The vascular repair method was determined based on an intraoperative assessment of the injured vessels. The decision of ligation was based on life-threatening hemorrhage and distal arterial circulation with more than one artery (Ulnar/radial and one of the tibia arteries). Venous injuries of large veins, especially to the femoral, popliteal and axillary veins, were repaired via simple repair, vein graft or PTFE graft methods, when possible. Other minor venous injuries were ligated.

During the initial evaluation in the emergency room, soft tissue defects and necrotic tissues in patients with limb injuries were scrubbed with 2000–3000 cc of Ringer solution and cleansed from foreign bodies prior to the operation. Subsequently, the necrotic tissue debridement, foreign body removal and soft tissue reconstruction performed after forceful irrigation with Ringer solution in the operating theater.

Low molecular weight heparin was given to all patients postoperatively for anticoagulation, and a dual or triple antibiotic regimen was applied postoperatively, based on the contamination and severity of the injury.

Fasciotomy was performed by orthopedists intra operatively or during intensive care unit follow up, according to the follow up of patient and operative management of injury. Nerve injuries were repaired either in the same session or delayed for two to three weeks, by orthopedists or neurosurgeons.

The demographics, treatment and early results (in hospital period; up to postoperative seven days) of patients were reviewed, and the studied variables included age, gender, clinical signs and symptoms on admission, anatomical region of vascular injury, mechanism of injury, concomitant injuries in polytrauma patients, Mangled Extremity Severity Score (MESS) [9], type of vascular repair and clinical outcome.

The data were analyzed using PASW Statistics software (SPSS Inc, USA), and was presented as mean (SD), range or numbers and percentage (%), as appropriate.

RESULTS

The mean age was 26.69±11.80 (7-66) years and 33 (91.66%) were male. The mean MESS score was 8.47±2.64 (3-14), and extensive tissue defect/loss was observed in 12 (33.33%) patients. The cause of injuries were shrapnel wound due to the bombing, stab wounds and gunshot (mostly rifle) wounds in 22 (61.11%), 3 (8.33%) and 11 (30.55%) patients respectively.

The anatomical localization of injuries presented in Table 1.

Table 1. Anatomical localization and repair methods of injured 73 vessels in 36 patients

Repair method **Vessel**	**n** *(73)*	**Primary repair** *(15)*	**Prosthetic graft** *(14)*	**Vein graft** *(21)*	**Ligation** *(23)*
Carotid artery	1				1
Subclavian artery	1		1		
Brachial artery	4	1		3	
Radial artery	3			2	1
Ulnar artery	3	1			2
Common Femoral artery	5		2	3	
Superficial femoral artery	8	2	3	3	
Profunda femoral artery	3	1		1	1
Popliteal artery	5		3	2

Posterior Tibial artery	4			3	1
Internal jugular vein	1				1
Subclavian vein	1	1			
Common femoral vein	7	4		1	2
Profunda femoral vein	3	1			2
Superficial femoral vein	7	3	3		1
Popliteal vein	4		2		2
Anterior tibial vein	4				4
Posterior tibial vein	4				4
Total (%)		20.54	19.17	28.76	31.50

Of the patients, high-energy injuries were observed in 24 (66.6%), medium-energy injuries in 2 (5.55%), low energy injuries in 3 (8.33%) patients and 7 (19.44%) patients had crush injuries (rescued from beneath the wreckage of collapsed buildings after the bombing). The number of patients with polytrauma was 29 (80.55%) and concomitant injury distribution of patients presented in Table 2.

In the study, 7 (19.44%) patients had isolated vascular injury; 12 (33.33%) patients underwent vascular surgery with concomitant active bleeding; 17 (47.22%) patients presented with hypovolemic shock upon arrival at the emergency room; ischemia signs were observed in 24 (66.66%) patients, and the mean ischemia time was 5.45 ± 5.20 (1-24) h.

Table 2. Concomitant injury distribution of 36 patients enrolled in the study

	n	%
Cranial injury	3	8.3
Neck injury	1	2.7
Chest İnjury	5	13.8
Abdominal injury	7	19.4
Pelvic injury	4	11.1
Lower extremity injury	28	77.7
Upper extremity injury	11	30.5
Large tissue defect	12	33.3

Of the patients, 25 (69.44%) had single extremity injuries, 9 (25%) had double extremity injuries and one patient had three extremity injuries. In 20 (55.55%) patients, extremity injuries were accompanied by bone fractures, of which 17 (47.22%) were open fractures.

Initial physical examinations revealed motor loss in 20 (55.55%) patients. Intraoperative nerve injury was mostly determined as a full-thickness incision in 12 (33.33%) patients. Three (8.33%) patients with polytrauma had postponed surgery decision after a follow-up period for repetitive physical examinations due to uncertain initial physical examination findings.

A total of 42 arterial and 31 venous injuries were observed in the operating theater. The most common repair method was graft interposition with autologous saphenous vein and PTFE. Ligation was the second preferred method, especially for venous injuries, and 31.50% of total injuries were ligated. The details of repair methods presented in Table 1.

Postoperative complications are listed in Table 3.

Table 3. Postoperative complications of patients

	n	%
Graft Thrombosis	4	11.1
Amputation	3	8.3
Mortality	5	13.8
Reperfusion injury	1	2.7
ARDS	1	2.7
MODS	1	2.7

ARDS: Acute respiratory distress syndrome, MODS: Multiple organ dysfunction syndrome

Thrombectomy and/or embolectomy performed for all postoperative graft thrombosis patients. Three patients had autologous vein graft thrombosis and one had a prosthetic graft thrombosis. The amputation rate was 8.3% (3/36). Two (5.55%) patients had secondary amputation after vascular repair and one patient with mangled extremity underwent primary amputation via an intraoperative multidisciplinary decision in order to save life. All three patients who underwent amputation had injuries of the popliteal artery including trifurcation.

The mortality rate was 13.8% (5/36), four of them had high-energy injuries and one had medium-energy injury. Furthermore, two patients with concomitant abdomen injuries died from sepsis, one patient with concomitant cranial injury died due to intracranial hemorrhage. Two patients in hypovolemic shock with concomitant large soft tissue defect underwent surgery with preoperative early intubation and died from acute respiratory distress syndrome and multiple organ dysfunction syndrome. A fasciotomy was applied to three patients, of which two were closed and one was open.

DISCUSSION

As reported variously, the incidence of war-related vascular injuries has been increased gradually from World war II (0.2-4%) to the wars in Afghanistan and Iraq (6.8 %), also a recent study from the Lebanon war reported that the rate of vascular injuries increased to 7.6% of all casualties, and to 10.8% in the soldiers [4, 10-12]. This increase is possibly correlated with shortened evacuation time, improved immediate resuscitation, damage control by the progressive and effective use of tourniquets and temporary shunts. Furthermore, these developments over years have brought improved life and limb rescue rates in war-related injuries [13-15]. In this civilian study, however, the distance to the war zone (15 min. away by road to the hospital) was the most important factor affecting the increasing admittance of war-related trauma patients.

Recent experiences have triggered the management of such injuries, assessing especially the effect of explosives on injury patterns and treatment strategies [3]. Explosive weapons are designed to increase the number and energy of casing fragments, leading to multiple penetrating wounds [16]. In the present study, most common injuries were shrapnel wounds from bombing and rifle wounds, hence these kinds of high energy injuries includes both penetrating and blast effects on tissues as designed. Therefore, vascular injuries associated with multiple trauma often lead to high mortality rates, unless prompt and appropriate surgical management is made [17], hence war-related injury treatment should be provided by surgeons with military surgery experience [6].

Vascular injuries of extremities are the most common type of injury in war-related trauma patients [3, 12-14], as is the case in this study and it may lead to limb loss or mortality. Bleeding may lead to hypovolemic shock, as was the case with 47.2% of the patients in the present study at the admittance. Consequently, the primary aim is to avert exsanguination and death, and then to restore blood flow to prevent amputation.

The initial physical examination of patients who present with hypovolemic shock may be misleading about vascular injury due to diminished or absent distal arterial pulse and inadequate perfusion of extremities. In patients suffering from hypovolemic shock, recurrent physical examinations are important, as in patients with soft signs, and also should be carried out after appropriate resuscitation of hypovolemic shock. Three polytrauma patients of this study underwent surgery through recurrent physical examination findings.

If the initial evaluation of a patient revealed hard signs of vascular injury with a single entry and/or exit wound, and with no concomitant injury, there is consensus on the decision to make an immediate vascular exploration after resuscitation in the emergency room. However, there is a lack of consensus regarding the management of patients with only soft signs in polytrauma patients complicated with concomitant injury, multiple extremity injuries or single extremity multiple segment injuries with soft or no signs of vascular injury [18]. For this grey zone of patients with soft signs, additional diagnostic methods such as angiography or CTA are required to be applied prior to surgery in hemodynamically stable patients, both for diagnosis and choice of treatment [19-21]. Of these, angiography is the optimum diagnostic method, although CTA has gained increasing value in diagnosis and treatment planning, therefore some studies reported that CTA should be considered as the first line modality [19].

In this study, patients underwent immediate vascular surgery on the basis of physical examination findings and hard signs of arterial injury with the goal of shortening the ischemic period. As neither angiography nor CTA was present, hemodynamically stable patients with soft signs of arterial injury were referred to a center where these examinations could be made. In a very small number of patients DUS could be used. In the absence of contrast imaging, physical examination findings with hard signs of vascular injury seem to be an effective means of diagnosis, although the need for contrast imaging methods for patients with uncertain physical examination findings of vascular injury is undisputed.

It should not be forgotten that the possibility of arterial trauma still exists, particularly in the upper extremities, with palpable distal arterial pulses [18-22], also impaired perfusions with absent distal arterial pulses may not be noticed due to of collateral circulation.

In this study, ligation of vessels was considered as the final option especially in hemodynamically stable patients, although ligation is a good strategy in selected vessels that do not cause distal extremity ischemia, and in cases of life-threatening bleeding.

Similar to other studies [3, 23, 24], superficial femoral, common femoral, popliteal and brachial arteries were the most commonly injured arteries in this study. Vein injuries are mostly accompanying with the adjacent artery injuries. The most common repair method of this study was saphenous vein graft interposition, as recommended in most studies [3, 25]. Applying a prosthetic graft is still a controversial issue, increased risk of thrombosis and infection, thus poor outcome with a high secondary amputation rate [17, 23, 26]. In this study, contrast with the previous studies the absence of early infection despite the high ratio use of prosthetic grafts may be attributed to the factors like; a large amount of wound irrigation as an initial response in the emergency department and also in the operating room, careful and aggressive debridement of necrotic and contaminated tissues, additionally use of dual or triple antibiotic regimen for the follow up. In contrast with expectations, the number of autologous vein graft thrombosis was higher than prosthetic grafts. Revascularization of these polytrauma patients was carried out initially, followed by bone and soft tissue operations. Therefore, thrombosis developed due to inadequate length (short/long) of the graft. No temporary vascular shunting was used in this study.

The amputation ratio relies on many variables, including the severity of limb injury, mechanism of the injury, ischemia time, existence of accompanying injuries, and disaster conditions when dealing with mass injuries [13]. In this study, three patients with popliteal artery injuries underwent amputation, one pediatric patient who had an ischemia time of 2h with MESS score of 9 underwent primary amputation by an intraoperative multidisciplinary decision in order to save life. The ischemia times of these three patients were found to be 2h, 4h, and 8h. The MESS scores of patients who underwent amputation were 9, 10 and 11 while the mean MESS score of this study was 8.47±2.64. During the treatment of mixed skeletal, vascular and soft tissue injuries, limb ischemia specifies the treatment primacy, and also high limb loss rates related with popliteal artery involvement [19]. The amputation rate of this study is close to previous studies reported in varying rates (3-20%) [27, 28]. Mortality rate (13.8%) of this study was higher than the varying rates (1.5% - 6%) have been reported in previous studies [28, 29].

Retrospective design of the study, short follow up period of patients and relatively small number of patients are the basic limitations of this study.

CONCLUSIONS

When dealing with war-related injuries, especially in polytrauma patients, occult vascular injuries have been possibly missed due to uncertain initial physical examination findings of vascular injury and frequently presents later. Therefore, the definite diagnosis of vascular injury should be revealed by angiography or CTA. Following the diagnosis, some critical decisions arising such as: which patient should be operated first, among who applied at the same time and requiring emergency surgical intervention; which one of the injury components should be operated initially in patients with polytrauma; which type of injuries of polytrauma patients should be operated by two different disciplines at the same time, in the same session; and also which type of injury can be delayed. These are challenging situations for even most experienced surgeons in patients with complex polytrauma accompanying with systemic effects. Therefore, a multidisciplinary approach should be used when establishing treatment priorities.

Civilian surgeons unexpectedly finding themselves acting war surgery with no background, hence may tend to make the same traditional mistakes that military surgeons have already learned from previous wars, nevertheless a rapid, careful multidisciplinary evaluation of experienced surgeons for the diagnosis and treatment priorities in war-related injury patients may lead to increase life and limb salvage rates.

Managing radial nerve injuries associated with humeral fracture

V. Cărbunaru, Alexandra Ciotei, Mihaela I. Zaharia

Abstract: *: The overall prevalence of radial nerve injury after humeral shaft fractures is up to 18% representing the most common peripheral nerve injury associated with long bone fractures.Spiral or oblique fractures of the junction between the middle and distal third of the humeral shaft are at greater risk for radial nerve injury. Iatrogenic damage to the radial nerve may also occur during manipulations of closed reduction.*

Material and methods: A prospective study between 2017-2019 following 5 patients (all male, with ages between 30 and 56 years old), who were treated at our clinic for complete radial nerve palsy after a high-energy fracture of the humerus

Results: All the patients were followed-up for a mean of 6 months (range 4 - 15 months) post op. The first 3 cases showed the initial signs of recovery 4 weeks after the operation. In the last 2 cases, a palliative radial intervention was required.

Conclusions: The consequences of the radial nerve palsy associated with humeral fractures is strongly related to trauma mechanism. In high-energy fractures, severe contusion or transection of the nerve must be expected. In this case, nerve recovery is unlikely and the patients should be informed of the poor prognosis and the need of tendon transfers.

Keywords: *humeral fracture, compression, upper limb, radial nerve, callus*

INTRODUCTION

Fractures of the humerus are often complicated with radial nerve palsy. The overall prevalence of radial nerve injury after humeral shaft fractures is up to 18% representing the most common peripheral nerve injury associated with long bone fractures.[1-5] This is caused by the relatively fixed position of the radial nerve and the direct contact with the periosteum of the humerus as the nerve courses through the middle and distal thirds of the upper arm and by the nerve's diminished mobility where it pierces the lateral intermuscular septum. As such, at this level the bone ends can easily entrap, contuse, or even lacerate the radial nerve, varying from neurapraxias to complete neurotmesis.

Spiral or oblique fractures of the junction between the middle and distal third of the *humeral shaft are at greater risk for radial nerve injury.[6] Iatrogenic damage to the radial nerve may also occur during manipulations of closed reduction or at the time of surgical intervention, during internal fixation with a intramedullary nailing or compression plate.[7, 8, 9]

Treatment is often expectant (non-operative), though surgery is also sometimes necessary by a variety of often imaginative procedures. Because radial nerve injuries are the least debilitating of the upper limb nerve injuries, results are usually satisfactory.[10]

PATIENTS AND METHODS

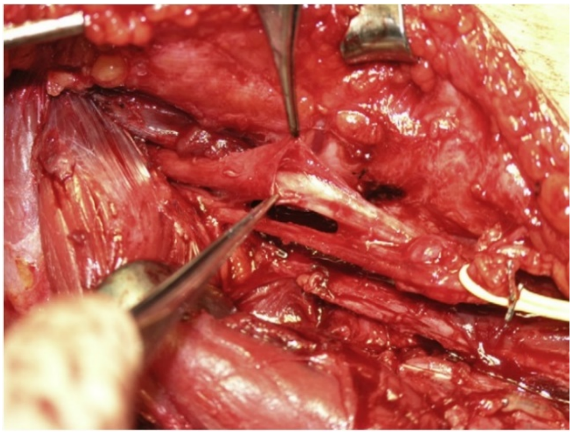
A prospective study between 2017-2019 following five patients (all male, with ages between 30 and 56 years old), who were treated at our institution for complete radial nerve palsy after a high-energy fracture of the humerus. In all cases, the fracture was stabilized and no other complications except the radial palsy. Baseline electrophysiological studies (i.e. nerve conduction velocity studies and electromyography) conducted before admittance showed a complete motor paralysis of the nerve and all had an absent Tinel's sign at each clinical examination.

Operative Procedure

Case 1: A 41-year-old male, with a 4 months old high-energy transverse diaphyseal fracture of the left humerus and faulty soft tissues following a car accident was treated with plating.

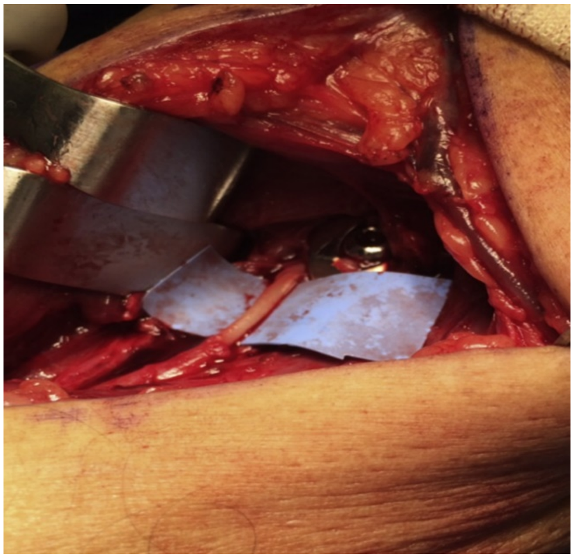
The same anterolateral approach used for plating was used during our surgical exploration where we found contusion of the radial nerve and perineurial adhesions of a small segment at the level of the humeral fracture (Figure 1).

Figure 1: Perineural adhesion of the radial nerve to the humerus



External neurolysis was practiced (Figure 2).

Figure 2: Neurolysis of the radial nerve



Case 2: A 38-year-old male, with 3 months old closed fracture of the right humeral shaft following a recreational arm wrestling match was treated with two non-staggered plates.

Upon surgical exploration via dorsal approach, a partially lacerated nerve draped over a loose compression plate.

Treatment associated the refixation of the plate and embedment of the nerve in the triceps muscle.

Case 3: A 40-year-old male, with a 3-month-old fracture of the humeral shaft following a car crush was treated with external fixator.

During surgical exploration, the distal pin of the external fixator was found to run through the brachioradial muscle into the body of the radial nerve destroying 15% of its circumference (Figures 3 and 4).

Figure 3: Distal pin winded up in the radial nerve

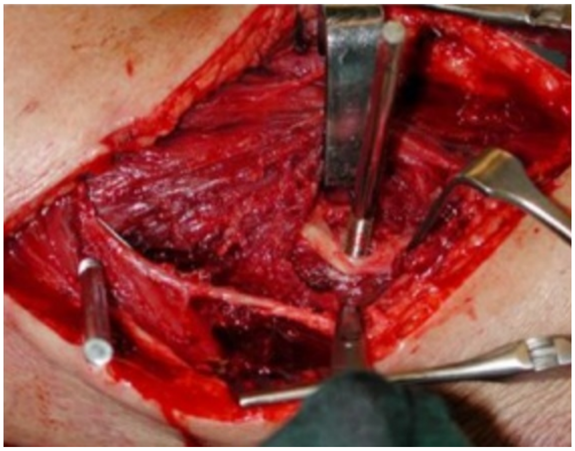


Figure 4: Radial nerve buried in the fracture callus

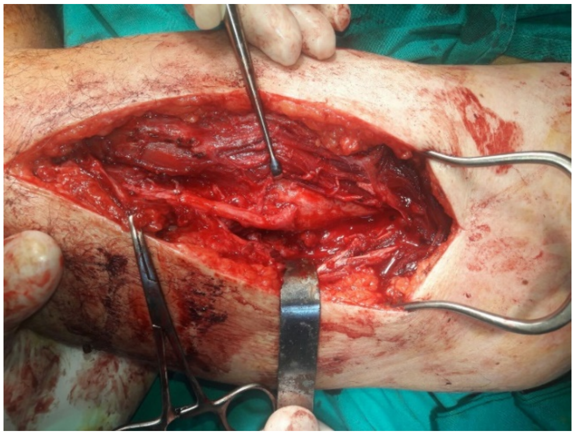
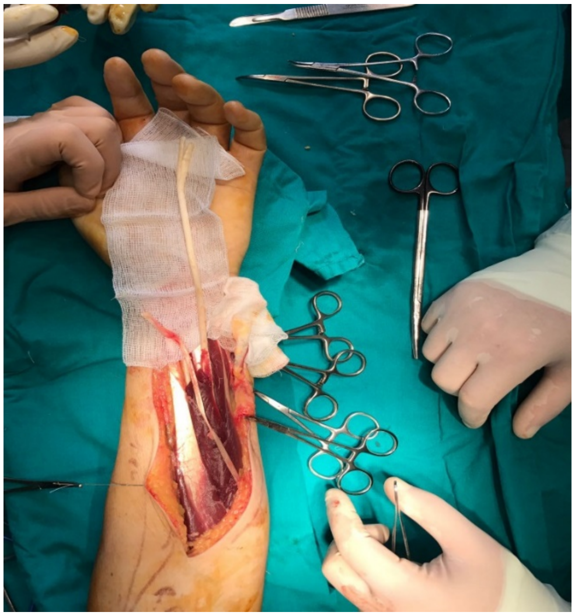


The pin was removed and reattached after releasing the nerve and embedding it in the triceps muscle.

Case 4: A 56-year-old male with a six-month-old fracture of the left humeral shaft was treated with internal fixation after crush in the conveyor belt.

Surgical exploration had a posterior approach through a lateral para-tricipital window revealing the nerve enveloped in the fracture callus more than 8 cm with the impossibility of finding the proximal end (Figure 5).

Figure 5: Presenting the donor tendons. From left to right: palmaris longus, flexor superficialis middle finger and flexor ulnaris carpi



A follow-up tendon transfer procedure was carried out flexor ulnaris carpi to extensor ulnaris carpi, flexor superficialis of middle finger to extensor digitorum communis, palmaris longus to extensor pollici longus (Figures 6 and 7).

Figure 6: Tenoplasty of the extensor digitorum communis and extensor pollici longus by Pulvertaft technique

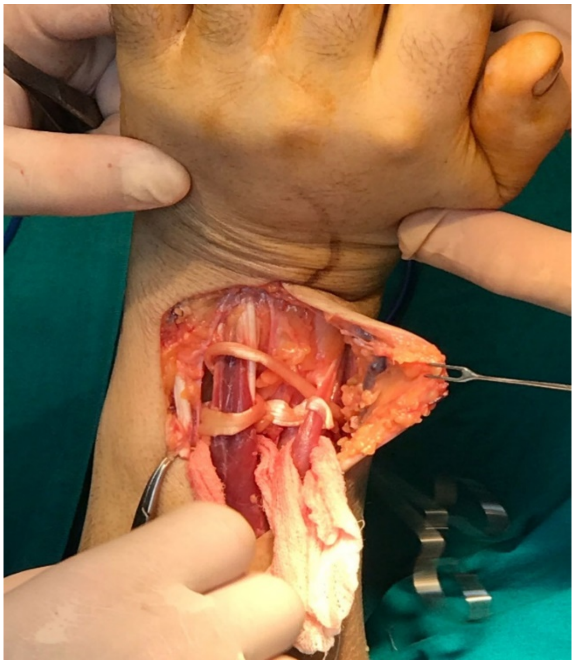


Figure 7: Active extension of the wrist, thumb and fingers 6 weeks post op

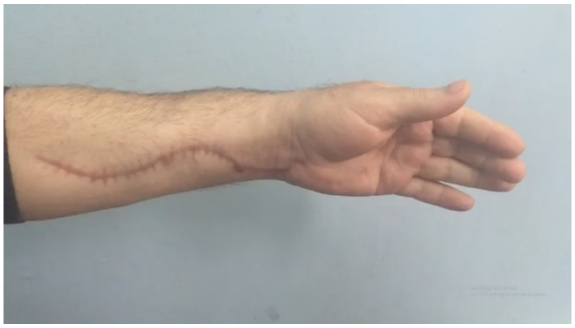

Case 5: A 30-year-old male, with a 12-month-old chainsaw trauma, which required open reduction and fixation of the humerus, anastomoses of the brachial artery with venous grafting and neurorrhaphy of median nerve and ulnar nerve, with the impossibility of finding the radial nerve ends, presented for second intervention in our clinic.

A palliative radial intervention practicing tendon transfer was used.

We transferred the pronator teres tendon to extensor carpi radialis tendon, flexor carpi radialis tendon to extensor digitorum communis and plamaris longus to extensor pollicis longus (Figures 8 and 9).

Figure 8: Presenting the donor tendons. From left to right: pronator teres, flexor radialis carpi and palmaris longus

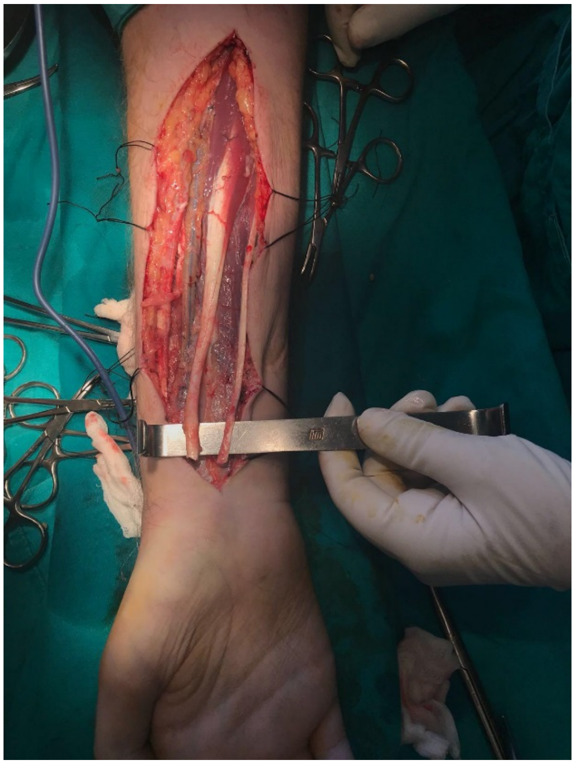

Figure 9: Tenoplasty of the extensor carpi radialis (over the scissors tip), extensor digitorum communis (forceps) by Pulvertaft technique

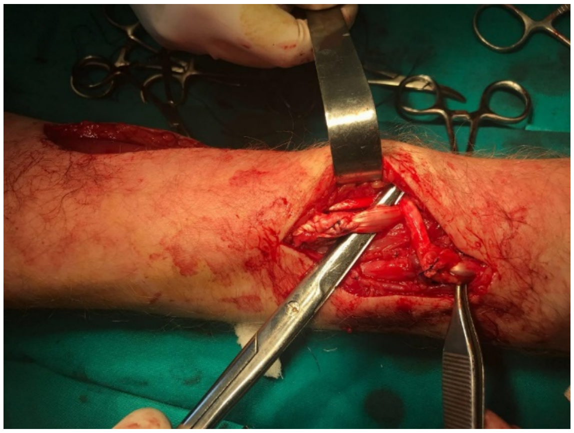

Postoperative follow-up examination included radiographic evaluation of the fracture, physical examination (i.e. Tinel's sign), and monthly electrophysiological studies for motor and sensory nerve recovery.

RESULTS

All the patients were followed-up for a mean of 6 months (range 4-15 months) post op. The first three cases showed the initial signs of recovery 4 weeks after the operation. Full nerve recovery was achieved in a mean of 19 weeks (range 16-22 weeks) with a slight sensory discomfort in the third case. An advancing Tinel's sign was a good predictor for nerve recovery.

In the last two cases where palliative radial intervention practicing tendon transfer was used, the imobilization was removed after approximately 4 weeks and a volar custom splint made by a hand therapist was applied with extension slings for the MP joint of the fingers. Active range-of-motion exercises of the fingers were begun at 3 to 4 weeks, and the wrist at 6 weeks.

Splinting as protection yielded excellent results and was done for 8 to 12 weeks postoperatively.

DISCUSSIONS

These cases highlights the necessity of a postreduction examination of the fracture. Nerve function should always be thoroughly assessed before and after reduction, with complete documentation in the medical record. To ensure accuracy, any patient who requires conscious sedation for reduction must return to full consciousness and alertness before obtaining the postreduction exam.

Radial nerve injury associated with a humeral shaft fracture is a very important injury pattern among trauma patients with an incidence up to 18%. [3] These injuries can be either primary or secondary depending on the timing of the palsy presentation. Early surgical exploration of the nerve is generally indicated for those cases, in which there was an open fracture, fractures that cannot achieve an adequate closed reduction requiring open reduction, fractures associating a vascular injury or a severe soft tissue injury [11].

Patients who demonstrate a primary radial nerve palsy have a reported spontaneous recovery rate of over 70% [12]. In the management of nerve palsy, nerve conduction examination with electrophysiological studies could be obtained at three months post injury, as motor potential should be recovered by this point, and these nerve conduction data will enable the clinician to determine if the injury should require surgical intervention. Early exploration revealing a nerve injury that can be repaired can lead to a quicker return to function and better nerve recovery. Degeneration of the motor endplate and irreversible muscle atrophy occurs if sufficient reinnervation is not present within 12–18 months after injury. [13] Poor functional recovery has been demonstrated in experimental studies when nerve repair is delayed for 6 months due to decreased motor neuron regeneration capacity. [14, 15]

Tendon transfer remains an essential technique in irreparable or long-standing radial nerve palsies for hand function restoration. Because the first signs of nerve recovery can be quite delayed, patience is merited before considering tendon transfers. A waiting period of 12 months is usually sufficient to see any evidence of nerve regeneration. Following a radial nerve injury, the extrinsic extensor function of the hand and wrist is lost, resulting in an inability to extend the fingers and wrist. It affects grip strength and has a large influence on thumb usage. Tendon transfer surgery must restore wrist, thumb and finger function without inflicting other motor deficits on the hand. [15] It is important that the joints have achieved good passive mobility in order to achieve optimal function post-tendon transposition. The donor muscles are tested for strength before surgery, and must come from a region unaffected by the pathology. [16]

Modern medicine sheds light on biological therapies and nerve regeneration. Research is being conducted with pluripotent stem cells and nerve conduits with promising developments using human amniotic membranes loaded with human umbilical cord mesenchymal stem cells in radial nerve repair. [17]

REVIEW

Manipulation of the gut microbiome may be a promising pathogenic approach in rheumatic inflammatory diseases – A review

Daniela Anghel[1,2], Oana G. Petrache[1], Mădălina E. Hoinoiu[1], Florentina Ioniţă Radu[1,3], Raluca S. Costache[1,3]

Abstract: *A symbiotic association between humans and microbes has been established over time. Disruptions in gut homeostasis have been linked to immune-mediated inflammatory diseases.*

Factors such as genetics, environment, diet, age, and medication play a major role in shaping the intestinal microbiome. An altered gut microbiome seems to modulate the progression and severity of inflammatory rheumatic diseases. Disruptions in the eubiotic state of the intestinal microbiome might promote intestinal and extraintestinal autoimmune and inflammatory disorders, although the mechanisms involved are not well understood.

In this review, we provide a general overview of several studies concerning intestinal microbiome perturbations and their implications in rheumatoid arthritis, ankylosing spondylitis, and systemic lupus erythematosus. Furthermore, we discuss the relationship between diet, intestinal microbiota, and inflammation.

Keywords: *intestinal microbiome, intestinal dysbiosis, probiotics, rheumatoid arthritis, ankylosing spondylitis, systemic lupus erythematosus*

INTRODUCTION

The human digestive tract is inhabited by somewhere between 300 and 1000 different species of bacteria. Microorganisms like bacteria, yeast, and viruses compose the gut microbiota. Bacteria are classified into phyla, classes, orders, families, genera, and species. [1]

There are four dominant bacterial phyla: Bacteroides spp., Firmicutes spp., Actinobacteria spp., and Proteobacteria spp. The Firmicutes phylum contains more than 200 genera such as Lactobacillus spp., Bacillus spp., Clostridium spp. (95% of the Firmicutes), Enterococcus spp., and Ruminicoccus spp. The Bacteroidetes phylum consists of predominant genera such as Bacteroides and Prevotella. Actinobacteria phylum is less abundant and represented by the Bifidobacterium genus. [2]

The relationship between humans and gut flora is a symbiotic one. The microbial colonization occurs before birth and stabilizes around the age of three. The intestinal microbiome has various roles: fermentation and degradation of dietary fibers, modulation of antibody production, defense against pathogenic bacteria colonization, production of vitamins, and maintenance of intestinal epithelium integrity.

The most important end products of microbial fermentation processes are short-chain fatty acids (SCFA), acetate, propionate, and butyrate. These molecules promote the immunity of the intestinal mucosa and protect it from pathogens. [3]

Only 1% of bacteria can be grown in cultures. New

[2] Titu Maiorescu University, Bucharest, Romania
[3] Carol Davila University of Medicine and Pharmacy, Faculty of Medicine, Bucharest, Romania

techniques like the extraction of DNA and the amplification of the 16S ribosomal RNA gene (rRNA) allowed researchers to analyze nucleic acids (DNA and RNA) from the stool. The Human Microbiome Project (HMP) focused on identifying, studying, and cataloging uncultivated bacteria.

The intestinal microbiome is influenced by diet and the environment. People who eat more carbohydrates and simple sugars have more Prevotella, while Bacteroides are associated with saturated fats and proteins. Plant-based diets are associated with a greater abundance of Prevotella and a greater diversity of microbes [4, 5].

It is believed that high-fiber diets ameliorate autoimmune, metabolic, and allergic diseases mainly through their microbiota dependent fermentation to SCFAs that promote tissue barrier integrity, mucus production, immune serum globulin (IgA) secretion, and regulatory lymphocyte T (Treg) differentiation, sustaining an anti-inflammatory environment [6].

Some microbes, such as Bacteroides fragilis, can drive the immune system to create anti-inflammatory cytokines while some segmented filamentous bacteria favor the production of pro-inflammatory cytokines. Bacteroides promote the production of immuno-regulatory T cells that suppress immune responses to self and bacterial antigens and stimulate epithelial repair. [7]

Manipulation of the intestinal microbiota through diet and probiotics may be the target for future strategies and preventive interventions in rheumatic diseases.

METHODS

Relevant literature relating to the gut microbiome and autoimmune diseases was selected through searching online medical databases. Search terms used were: “intestinal microbiome”, “gut microbiota”, “intestinal dysbiosis”, “manipulation of the gut microbiome”, “rheumatic diseases and intestinal microbiome”, “probiotics”. Only English-written studies published from 2011 to date were selected and analyzed.

RHEUMATOID ARTHRITIS (RA)

Rheumatoid arthritis is a chronic, autoimmune disease that primarily affects joints and the first study that links intestinal microbiome to arthritis was published in the late 1970s, suggesting that bacterial flora may be a stimulus for induction of cell-mediated immunity and may also have suppressive effects on the disease evolution. [8]

The patient microbiome plays a big role in the progression of rheumatoid arthritis. Together with the lymphoid tissue, the microbiome helps maintain immune homeostasis. Changes at this level can damage the intestinal mucosa and the systemic immune system, triggering the onset of autoimmune diseases.

Using zonulin as a serological marker, some recent studies have demonstrated the increased gut permeability in rheumatoid arthritis patients. This finding has been shown in about 1/3 of pre-RA patients. [9]

In rheumatoid arthritis, studies have shown that patients present a dysbiotic state, with the depletion of gram-negative bacteria and an increase of gram-positive bacteria. Furthermore, these patients present a higher concentration of Collinsella and Eggerthella lenta than normal individuals. [10]

As well, these patients have a high level of Prevotella copri and a low level of Bacteroides. P. copri pathogenicity was explained through its capacity of stimulating Th1 cells. Some patients produce antibodies against P. copri (IgA, IgG). Moreover, an over-abundance of P. copri has been identified in individuals at risk of rheumatoid arthritis (patients without arthritis but anti-citrullinated protein antibody – ACPA/ rheumatoid factor – RF positive). [11, 12, 13]

A study showed that a Prevotella strain, Prevotella histicola, suppresses arthritis in humanized HLA-B27 mice. [14] P. histicola treatment can reduce pain and improve motor function as a response to an increase in T regulatory cells and a decrease in IL-6 levels. [15]

Lactobacillus salivarius is more abundant in rheumatoid arthritis patients but its effects are unclear. Administration of L.salivarius in mice showed a significant improvement of collagen-induced arthritis and it may help reduce interleukin-17 and increase anti-inflammatory interleukin-10. Thus, it may help reduce clinical manifestations in RA patients. [16]

A study conducted on 60 women with rheumatoid arthritis, showed the beneficial role of Lactobacillus casei. Used as adjuvant therapy, it reduces the symptoms, lowers the pro-inflammatory cytokines, and lowers serum C - reactive protein and DAS28 score. [17]

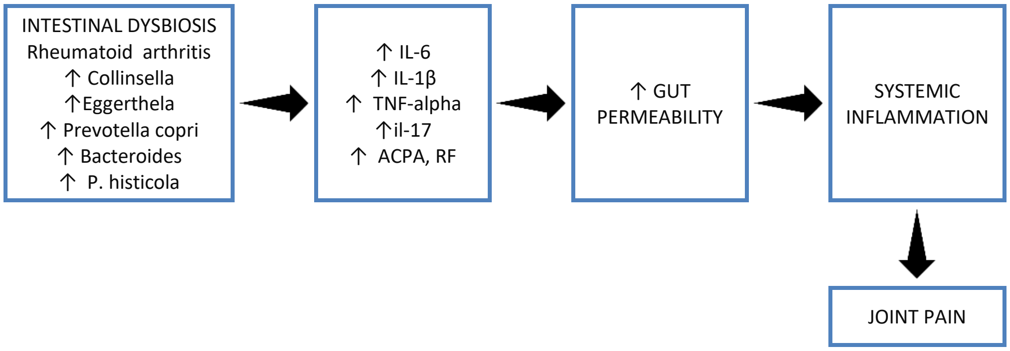
A more recent study, conducted on P. histicola treated mice, showed a decrease in the incidence and severity of arthritis. P. histicola decreases the intestinal permeability and lowers the pro-inflammatory IL-17 cytokine and increases IL-10. [14] Because P. histicola is normally present in the gut, the treatment as a probiotic in humans is beneficial, with minimum adverse effects.

A study conducted in China found a greater abundance of

Enterobacteriaceae spp. and Klebsiella spp. and a lower abundance of Bifidobacterium spp. in rheumatoid arthritis patients with high levels of TNF-α or IL-17A. Moreover, ACPA-positive patients had a greater abundance of Blautia spp., Akkermansia spp. and Clostridiales spp. then patients with negative ACPA. In conclusion, patients with RF/ACPA seropositivity exhibited a different microbial composition than RF/ACPA negative patients, suggesting an association between intestinal microbiome alteration and disease activity. [18]

Porphyromonas gingivalis, a periodonthopathogenic bacteria that exist in dental plaque can be swallowed with saliva and can affect the composition of the gut microbiome. Several studies have shown a strong correlation between P. gingivalis infection and systemic disease. Intestinal dysbiosis by oral inoculation of P. gingivalis has been shown to contribute to the progression of arthritis. [19, 20]

Figure 1: Associated microbiome in rheumatoid arthritis



Rheumatoid arthritis treatment and intestinal microbiota

The use of disease-modifying anti-rheumatic drugs (DMARDs) can modulate the intestinal microbiome and has the potential to shift the intestinal flora towards a healthy microbiome.

Two studies showed a significant decrease in Bacteroides fragilis and an increase in Prevotella maculosa after treatment with Methotrexate (MTX). Dysbiosis associated with RA was partially resolved after treatment. [21, 22] Another study suggests that patients that were treated with Methotrexate showed increased species richness and diversity compared to other patients receiving different treatments. [23] These studies suggest that MTX could correct intestinal dysbiosis.

Some studies concluded that pharmacological treatment in rheumatoid arthritis increased the Firmicutes and Bacteroidetes phyla. MTX induced a significant growth in Firmicutes over the Bacteroidetes that was associated with improved drug response and reduced inflammation. [24, 25] In a study conducted in 2018, the microbial profile of Etanercept treated patients (in monotherapy or combination with Methotrexate) was compared to normal individuals. There has been reported a significant decrease of Faecalibacterium compared to healthy individuals. In Etanercept treated patients there has been reported a great abundance of Cyanobacterium compared to patients without treatment.

Some species of Cyanobacterium produce some metabolites and bioactive substances that have cytotoxic properties and are involved in gastroenteritis. On the contrary, some metabolites have anti-inflammatory and immunosuppressive properties that are beneficial in rheumatoid arthritis. [26]

ANKYLOSING SPONDYLITIS (AS)

Ankylosing spondylitis is a chronic, autoimmune disease characterized by long-term inflammation of the sacroiliac joints and spine with or without HLA-B27. But the most important genetic factor in ankylosing spondylitis, HLA-B27, could change the intestinal microbiome, contributing to multisystemic inflammation and the production of IL-23 and other proinflammatory cytokines.

HLA-B27 positive patients had changes in Faecalibacterium prausnitzii, Bacteroides vulgares, and Akkermansia muciniphila. An abundance of Bacteroides vulgatus has been discovered in HLA-B27 rats, suggesting that HLA-B27 may alter the intestinal microbiome composition. [27]

In ankylosing spondylitis, 87% of the patients have an altered microbiome (dysbiosis). Their microbiome was characterized by an abundance of species of Proteobacteria spp., Enterobacteriaceae spp., Bacilli spp., Streptococcus spp., Actinobacteria spp. and a low number of Bacteroides and Lachnospiraceae. [28] Dysbiosis is also associated with disease activity.

Akkermansia muciniphila, of the phylum Verrucomicrobia spp., resides in the mucus layer of the large intestine. It is implicated in maintaining intestinal integrity and can cause the degradation of the mucin in the gut epithelium. [29]

Prevotella can increase Th17-mediated immune response in the intestinal mucosa. Increased Prevotella abundance stimulates the production of IL-1, IL-6, IL-8 and also stimulates neutrophil recruitment. The mucosal inflammation caused by Prevotella leads to systemic dissemination of inflammatory mediators and promotes chronic inflammation. [30]

Some microbes, such as Faecalibacterium prausnitzii, administered to mice, have been found to protect them against induced intestinal inflammation, thus concluding that F. prausnitzii has anti-inflammatory effects. [31] A decreased abundance of F. prausnitzii was observed in fecal samples of patients with ankylosing spondylitis. [28, 32]

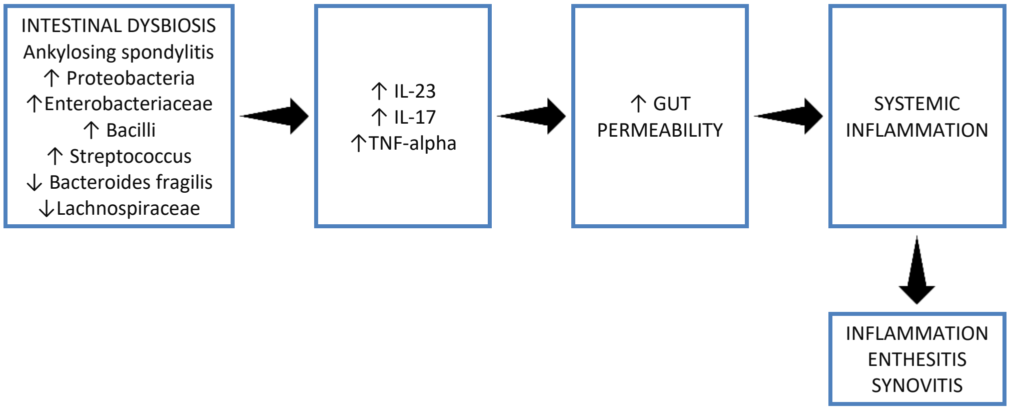


Figure 2: Associated microbiome in ankylosing spondylitis

Ankylosing spondylitis treatment and intestinal microbiota

Patients with ankylosing spondylitis treated with biological treatment have shown a greater abundance in Proteobacteria spp. (especially the Enterobacteriaceae family) and Veillonella genus compared to patients without treatment. [33]

A perturbation of the intestinal fungal microbiome (mycobiome) has been observed in patients with ankylosing spondylitis after biological treatment. An increase in the abundance of Saccharomycetales was found after anti-TNF and anti-IL17 treatment. [34]

SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Systemic lupus erythematosus is an autoimmune disease that is characterized by severe inflammation that can affect almost all organs of the body. Lopez et al. observed the influence of the microbiota over T lymphocyte differentiation in healthy and SLE groups. These authors found a rise in lymphocyte activation and differentiation toward Th17 in SLE patients. [35]

There were some studies on SLE patients which demonstrated that the abundance of Firmicutes is decreased and that of Bacteroidetes is increased compared to healthy control groups. If the intestinal epithelial barrier is damaged, Enterococcus gallinarum and Lactobacillus reuteri, possible gut pathobionts, can translocate into the systemic tissue, inducing autoantibody production. In addition, Ruminococcus gnavus can trigger an anti-double-stranded DNA antibody response. [36, 37]

A study conducted in Spain has proved that there is a gut microbial dysbiosis related to SLE in Caucasian female patients. SLE patients developed intestinal dysbiosis with a decrease within the Firmicutes spp. and a rise in the Bacteroides spp. It also showed that SLE patients with inactive lupus disease had significantly lower Firmicutes/ Bacteroidetes ratios than healthy control individuals did. [38]

A study conducted by Van der Meulen et al also showed that in SLE patients, the intestinal microbiota composition is characterized by lower bacterial richness, lower Firmicutes/ Bacteroidetes ratio, and a greater abundance of Bacteroides species. [39]

Similarly, a study by Greiling et al concluded that the Firmicutes/Bacteroidetes ratio in SLE patients decreased compared to healthy controls. In addition, commensal bacteria which contain Ro60 orthologs could induce the production of autoantibodies that cross-react with human Ro60, therefore triggering autoimmune diseases like SLE. [40, 41]

On the contrary, a study concluded that Firmicutes/

Bacteroidetes ratio is not significantly different between SLE patients and healthy controls. Also, this study concluded that Gram-negative bacteria, like Proteobacteria spp. and Blautia spp. were increased and Odoribacter spp. was decreased in SLE patients. [42]

A study explored whether the alteration of the intestinal microbiome in SLE patients from China was according to the intestinal dysbiosis of SLE patients from Spain. The depletion of Firmicutes spp. and the abundance of Bacteroidetes spp. in SLE patients from China was in keeping with the SLE patients from Spain. This study also showed that nine genera of intestinal microbiota were SLE-related microorganisms: Rhodococcus spp., Eggerthella spp., Klebsiella spp., Prevotella spp., Eubacterium spp., Flavonifractor spp. and Incartae spp. sedis were found in great abundance but Dialister spp. and Pseudobutyrivibrio spp. were depleted in SLE subjects. These nine genera have the potential to distinguish SLE patients from healthy controls. Also, the gut microbiome profiles of SLE patients were found to be more influenced by disease than ethnicity. [43]

Another study conducted in China concluded that the genera Streptococcus spp., Campylobacter spp., Veillonella spp. and the species Anginosus spp. and Dispar spp. were in direct correlation to lupus activity, while the genus Bifidobacterium spp. was in negative correlation to the disease activity. [44]

A study conducted in New York, on SLE female patients, investigated the fecal microbiota for possible pathobionts. Patients with a high disease activity index had a greater abundance of Ruminococcus gnavus. The highest levels of serum anti-Ruminococcus gnavus strain-restricted antibodies were found in patients with active nephritis. These findings showed evidence of altered fecal commensal taxa and increased immunoglobulin levels and other biomarkers, as evidence of altered gut barrier function. The study concluded that some strains can contribute to the immunological pathogenesis of lupus nephritis. [45]

Treatment with probiotics composed by Lactobacillaceae members has been used as anti-inflammatory therapy. Studies found the up-regulation of anti-inflammatory cytokine genes and down-regulation of the pro-inflammatory ones.

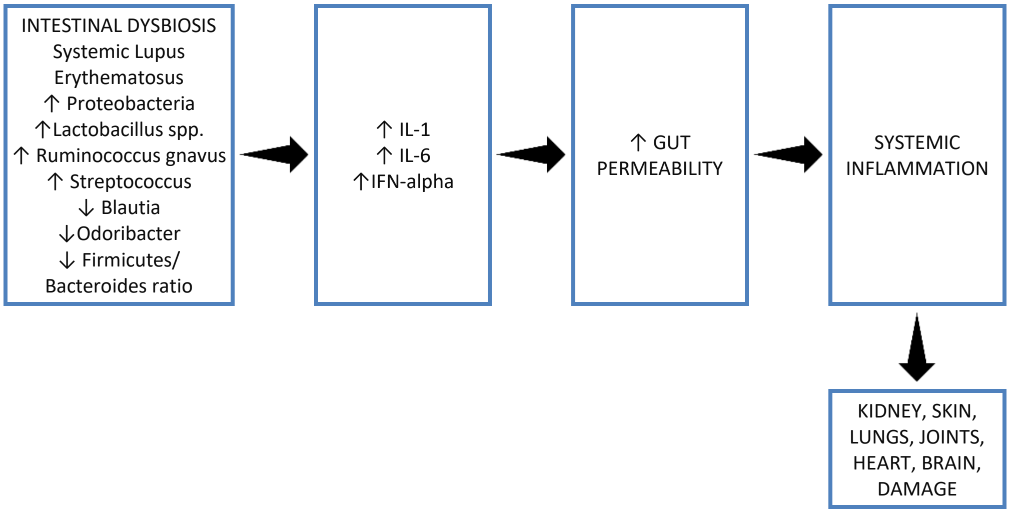
Moreover, the probiotic-treated group exhibited higher anti-oxidant activities and low levels of lipid peroxides. CRP levels were found to be in the normal range in comparison with the untreated group which levels were elevated.

Immunohistochemistry found high levels of IL-10 and low levels of IL-6, demonstrating the anti-inflammatory properties of L. mucosae and L.fermentum. [46, 47]

Lactobacillus rhamnosus and Lactobacillus delbrueckii have been found beneficial in the management of newly diagnosed SLE patients. [48] L. rhamnosus stimulates IL-12 and IL-10 production. Moreover, it secretes soluble factors that decrease TNF-α production, a potent pro-inflammatory cytokine. [49]

Although there is still no clarity about the role of microbiota within the development of SLE, the evidence suggests that the dysbiosis observed within SLE patients might be associated with this disease.

Figure 3: Associated microbiome in systemic lupus erythematosus



Systemic lupus erythematosus treatment and intestinal microbiota

Nonselective immunosuppressive therapies, like Dexamethasone and azathioprine, in SLE patients, may have vast effects on the intestinal microbiome. It is believed that at the same time as immunosuppressive medications are acting directly onto suppressing inflammation, these medications can also help in the formation of a microbiome that promotes the regulation of local inflammation within the bowels and potentially at distant sites within the body. A study showed that the gut microbiota tended to be more diverse after Dexamethasone treatment. Also, a greater abundance of lactobacilli was found after the treatment with Dexamethasone. [42]

On the contrary, no significant results were found between gut microbiota and methotrexate use in a recent study within the British TwinsUK cohort. [39] Chloroquine and hydroxychloroquine are reported to inhibit the intracellular growth of bacteria in vitro, but these drugs do not seem to own any antibacterial activity or effect on extracellular bacterial growth. Regarding the use of NSAIDs, a study observed no significant effect on the gut microbiome. Also, oral corticosteroid use didn't significantly affect the gut microbiome. [50]

DIET

Diet and the intestinal microbiota may be the target for future treatments and preventive interventions in rheumatic diseases. Diet can modulate the symptoms in rheumatoid arthritis through the metabolites produced by the intestinal microbiome. The intestinal microbiome has the capacity of modifying the circulating pro and anti-inflammatory mediators. [51]

Western diets are characterized by increased consumption of refined carbohydrates, red meat, and salt, which can induce a pro-inflammatory state and trigger the onset of autoimmune diseases. [52, 53]

Patients with a positive rheumatoid factor or anti-citrullinated protein antibody had a decreased concentration of omega-3 fatty acids in the red blood cell membranes, suggesting the potential beneficial effect in individuals with genetic susceptibility to rheumatoid arthritis. [54]

Some studies suggest that there might be a link between high salt consumption and the increasing incidence of autoimmune diseases, especially rheumatoid arthritis. A high concentration of sodium chloride can induce the activation of some signaling pathways, the activation of Th1, the overproduction of pro-inflammatory cytokines (IFN-gamma, IL-17), and the differentiation of macrophages. [55, 56]

For example, trimethylamine-N-oxide, a pro-inflammatory metabolite that derives from choline and carnitine, found in red meat, eggs, and dairy, is produced by Prevotella copri. [57][58]. Prevotella copri was found in great concentrations in newly diagnosed patients with rheumatoid arthritis. [59]

Probiotic use of Lactobacilli spp. improves intestinal immune function and stimulates anti-inflammatory cytokines (IL-10).

In general, Lactobacillus spp. and Bifidobacterium spp. are considered beneficial. Both species produce catabolites that decrease intestinal permeability and have anti-inflammatory and antioxidant properties, with the enforcement of the intestinal barrier function. Fermented foods that contain Bifidobacterium spp. and Lactobacillus spp. genera can have a protective role against immune-mediated diseases. [60]

A study evaluated the effects of L. casei supplementation on disease activity and inflammatory markers levels in rheumatoid arthritis females. A decrease in CRP, DAS28, and inflammatory cytokines was observed. [17]

The microbial degradation of complex carbohydrates will increase short-chain fatty acids that are beneficial for the intestinal immune response. [61] Several foods (highly refined flours, gluten, saturated and trans fats, red meat, dairy) have been identified as proinflammatory foods. Some vegetables as tomatoes, eggplants, and potatoes, contain solanine and increase intestinal permeability.

Foods high in omega 3 (chia seeds, flax seeds, sesame seeds, avocados), fruit that contain enzymatic proteins (pineapple, mango, papaya), turmeric, black pepper, green tea, and legumes offer multiple benefits.

To decrease inflammation, an ITIS diet has been suggested. It consists of a modified Mediterranean diet with several changes: the separation of carbohydrates and proteins, gluten-free foods, fruit with enzymes, and other anti-inflammatory foods mentioned above. [62]

A study regarding intestinal microbiome and Mediterranean diet observed that an increased ratio of Firmicutes/ Bacteroides was related to lower adherence to the Mediterranean diet. A lower animal protein intake was associated with an abundance of Bacteroides. Moreover, high consumption of sugars, saturated fats can affect the intestinal microbiota diversity. A plant-based diet was related to higher bifidobacterial counts. [63]

A case report discussing a fecal matter transplant (FMT) for a rheumatoid arthritis patient found that HAQ-DI (Health

Assessment Questionnaire – Disability Index) dropped seven days after FMT. [64] Therefore, fecal matter transplant may be an effective treatment for rheumatoid arthritis through the restoration of beneficial microbiota.

DISCUSSIONS

The treatment in rheumatology has made great advances with the potential to significantly impact the evolution of inflammatory diseases. A promising area of active research is the targeted manipulation of the microbiome to improve the outcome of rheumatic diseases.

The Fecal Matter Transplant in rheumatic diseases is not studied enough and more data is needed to achieve durable responses. Extensive donor testing is mandatory to guarantee patients' safety.

The use of prebiotics and probiotics can promote the growth of beneficial microbes. Probiotics supplements may be used as adjunctive therapy for rheumatic patients.

The microbiome composition can be used for prognosis and diagnosis, but most importantly, the manipulation of the intestinal microbiome through diet may be a promising future therapeutic approach. Large, long-term clinical trials are needed for specific dietary recommendations to rheumatic patients.

CONCLUSIONS

Current literature shows the link between the intestinal microbiome and the activity and severity of rheumatic diseases.

The imbalance of bacterial phylum, especially Firmicutes spp. and Bacteroidetes spp., is believed to be one of the most important causative factors for autoimmune diseases.

Although a lot of progress had been made in the past years regarding the intestinal microbiome, the research still requires more data. Targeted manipulation of the intestinal microbiome is needed for better treatment and management of inflammatory rheumatic diseases. Although 16S rRNA sequencing provides information about microbial identity, its function remains unknown.

Fecal matter transplant may have a good therapeutic effect on rheumatic diseases through its capacity of restoring and maintaining eubyosis.

Diet has been shown to influence the evolution and severity of autoimmune diseases. The use of pre and probiotics may be useful. The use of Lactobacillus species, as an adjuvant treatment, has been found beneficial.

Dietary or targeted manipulation of the intestinal microbiome may restore homeostasis and restrain disease-promoting pathobionts.

Mass shooting incidents: evolution of preventive procedures, preparation, treatment, and medical care supply

Symeon Naoum[1], Vasileios Spyropoulos[1]

Abstract: *Mass shootings incidents occur with increasing frequency over time. Studying these cases proved that, despite their diversity, several common features could be taken into account in the early detection and possible prevention of certain future cases. Accepting that such incidents may occur anywhere and anytime, societies need to be prepared for their more effective response. Informing citizens about the best way to react to a mass shooting event is considered crucial and essential. The "Run-Hide-Fight" guideline/directive seems to be the most appropriate guideline given to the public. Proper training, of both the Suppression Forces and the emergency medical care providers, is considered of utmost importance. The role of the Incident Commander, regarding the incident management, as well as the external bleeding control of the injured people, are factors of paramount importance in trying to mitigate the casualties from such an incident. The alertness of both citizens and organizations/structures may lead to early detection of potential perpetrators and thereby averting a mass shooting incident. To achieve increased survival and a reduced number of casualties from a mass shooting event it is vital proper education be present at all levels. The response to a mass shooting event should be imprinted in an Emergency plan. Such a plan should have been decided and made, by the Security and Suppression Forces, the Healthcare Institutions, and the Public Safety Answering Point.*

Keywords: *mass shooting incident, first responder, active bleeding, tourniquet, Incident Commander*

INTRODUCTION

Although mass shootings incidents have taken place throughout recent world history, the literature has been relatively limited, as such incidents were more sporadic before the 21st century [1]. A mass shooting incident is usually the result of one or more people killing or attempting to kill people within a limited and inhabited area. In most cases, the perpetrators use firearms/guns and there are no specific models for victim selection [2]. The immediate response as well as the perpetrators' neutralization are required to mitigate the consequences and casualties. However, because it will be some time before specialized forces arrive at the scene and take action, the way surrounding people react to such an event is of equal importance.

The purpose of this review is to present both the most appropriate ways of prevention and preparation, as well as the optimal procedures for responding and dealing with possible mass shooting incidents. Informing, preparing, and training citizens and stakeholders such as the Suppression Forces and emergency medical care providers, is crucial in reducing the casualties in a mass shooting incident in an

urban environment.

DEFINITIONS

A mass shooting event involves multiple incidents of violence with a firearm/gun. However, there is not a widely accepted definition of the term "mass shooting incident". The US Federal Bureau of Investigation (FBI), for instance, does not use the term "mass shooting incident", but refers to these incidents as "active shooter incidents" [2]. FBI, therefore, defines as an active shooter "a person who is actively involved in a murder or attempting to kill people in a residential area", while it also defines as mass murder "four or more murdered during an event without time distinction (cooling-off period) between murders" [3]. The United States Congressional Research Service (CRS) acknowledges that there is not a universally accepted definition and describes as a mass shooting incident "an event in which a perpetrator selects four or more individuals and kills them indiscriminately", adding to the FBI's definition the word "indiscriminately" [4]. The Gun Violence Archive (GVA), a non-profit organization that has been monitoring gun violence in the United States since 2013, describes as a "mass shooting event" four or more people killed in a single incident at the same time and location, not including perpetrator [2,3]. Moreover, this organization does not exclude situations such as domestic violence, gang activities, etc., nor does it differentiate victims depending on the circumstances under which they were shot, which means that its definition is broader than of other organizations and therefore includes incidents that are not recorded in other databases. Meanwhile, in 2013, the United States Congress defined mass murder as "three or more murders in a single incident" as part of a bill to enable the Department of Justice to assist local authorities during the investigations [2].

STATISTICAL DATA

The vast majority of mass shooting incidents have taken place in the United States of America [5]. According to GVA, from 1st August 1996 until December 2019, a total of 172 cases have been reported [6]. In just a few of these cases, the perpetrators were two, while no incidents involving robberies or domestic violence were reported. A total of 1228 people were killed, coming from almost all races, religions, socioeconomic status, and age. Of these, 196 were children and adolescents. Also, thousands of survivors with permanent disabilities and serious physical and mental health problems should not be omitted [6]. Perpetrators often used or carried more than one weapon, while in a case one perpetrator was found carrying 24 weapons. Of the total 326 weapons used in the above-mentioned incidents, 179 were legally acquired (55%), 61 were illegally acquired (19%), while it is not clear how weapons were acquired in 86 cases (26%). Of a total of 179 perpetrators, some were known to have violent tendencies or criminal history records, but there were also several who had not presented any criminal behavior at the time of the incident. The vast majority (99%) were men and most were 20-50 years old. More than half (55%) lost their lives on or near the scene of the incident, often by committing suicide. Lastly, incidents in schools and places of worship tend to come first in the public's memory but are a relatively small part of mass shooting incidents. The most common are those in offices, shops, and restaurants with the State of California having the most such attacks (29) of any State [6].

According to the FBI, after 2011 the frequency of mass shooting incidents has increased, with the period 2011-2014 occurring almost three times as many as in previous years [7]. During 2000-2013, a total of 160 cases (according to the wider definition than the GVA's definition) were recorded, with an average of 11.4 cases per year. According to the same report, 16.9% of attacks took place in schools and 45.6% in shops and markets. 90 of the above mentioned 160 incidents, were completed before the Suppression Forces even intervened, most often with the perpetrator's suicide. Of the 64 cases in which the duration of the incident was ascertained, at 44 (69%) the incident was completed in less than five minutes, while at 23 (36%) in less than two.

Mass shooting events are expected to occur worldwide. Two of these incidents received worldwide publicity, evolving many victims: on November 13th, 2015, a total of nine perpetrators launched an attack in Paris, killing a total of 130 people and injuring more than 350 [8], while on New Year's Eve 2017 in Istanbul, a perpetrator stormed a nightclub, killing a total of 39 people and injuring another 79 [9]. In both cases, there was a religious or racist motive.

PERPETRATORS' CHARACTERISTICS

To increase the chances of an early potential perpetrators' detection, both mass shooting events and perpetrator's physiometric characteristics have been studied [10]. According to an FBI study, regarding the pre-attack behavior of perpetrators in the United States for incidents that happened in 2000-2013 [11], the majority of perpetrators had exhibited 4 to 5 worrying-suspicious behaviors before the attacks. For perpetrators under the age of 18, these behaviors were more likely to have been noticed by classmates or teachers than by the family environment. Each perpetrator was exposed to an average of 3.6 stressors during the year before the attack. Of the cases in which some kind of suspicious behavior was observed, 54% did not take any action, while 41% of them were reported to authorities. According to the same study, in most cases (64%) at least one of the victims was pre-selected by the perpetrator [11].

As far as the age of the perpetrators is concerned, the youngest reported to be 12 years old and the oldest 88, with the average age of 37.8 years (94% were men and 6% women). Of the adult perpetrators, 20% were high school graduates, while 34% had completed at least an Institute of Technology or University. Of the latter, 5% were Master's Degree or Ph.D. holders. However, there was a significant percentage (36%) where the level of education could not be ascertained. 38% of the adult perpetrators were unemployed while 44% were workers. The remaining 19% included students, retirees, people with disabilities, etc. The 24% of adult perpetrators, at the time of the attack or in the past, were involved in some way with the Armed Forces or Security Forces, while 14% of perpetrators had one or more convictions before the attack [12].

The above-mentioned study also investigated two related but distinct time variables: a) the time the perpetrators spent planning the attack and b) the time they spent preparing it. The first category concerns the time from when the perpetrator began to think about a possible attack until its implementation. Because it is often difficult to determine its onset, in many cases this period could not be determined by the researchers. The second category is more specific, usually less than the first, and concerns the time from taking any kind of action by the perpetrator (eg gathering of relevant material, a supply of weapons and other equipment, etc.) to the implementation of the attack. In terms of design, 26% of the perpetrators took 1-2 months, 18% 3-5 months while 24% less than a week, with half of them less than just twenty-four hours. In terms of preparation, 28% needed a maximum of one day, 26% 1-7 days and only 4% consumed 6-12 months. The study also explored how perpetrators supplied the weapons they used. In 40% of cases, the perpetrator had obtained the weapons of the attack legally, 2% bought the weapons illegally, in 6% of cases the weapon was stolen, while in 11% it was borrowed. Besides, it seems that the majority of the perpetrators acted in a place known, if not familiar, to them.

This study also investigated the presence of stressors in perpetrators' lives. These included financial problems, physical and mental health issues, interpersonal conflicts with family, friends, colleagues, as well as alcohol abuse or drug use. The study acknowledges that many people occasionally face similar issues, but most have mechanisms (personality, psychological flexibility, interpersonal relationships) to cope effectively. Although the issue is multifactorial, it appears that the perpetrators usually experienced multiple stressors during the period before the attack (an average of 3.6 within the last year). The most common stressor detected was a mental health disorder in 62% of perpetrators. About half (49%) had financial problems, while 35% had work-related problems. In 34% of cases, serious family issues were reported, while 22% of the perpetrators were addicted to alcohol or drugs. Only 2% of the operators did not detect any of the studied stressors. Given that mental health disorder was the most common stressor, as well as the fact that it is a fairly broad and varied term, it is worth mentioning that of all cases in which mental health disorder was detected, only in 41% of cases, perpetrators had a previous official diagnosis by a health professional, with the 75% being diagnosed as a “mood disorder”.

Another interesting aspect of the study was the research for cases in which people from the perpetrator’s environment had found some kind of worrying behavior during the period before the attack. Thus, in 62% of the cases, deviant behaviors were observed from a psychological standpoint, in 57% interpersonal disorders, and in 54% of cases a problematic way of communication. Moreover, in 46% of perpetrators who were workers, there was a decline in performance at work and in 42% of those who were students, there was a corresponding decline in school performance. However, it is worth noting that, contrary to the common belief that the perpetrators of such attacks tend to be isolated, the study found that 68% of adult perpetrators lived with other people immediately before the attack. Additionally, 86% of the perpetrators were found to have a significant social relationship and contact with at least one person in the year before the attack.

So that research data be used for prevention, not only was it investigated when some deviant behavior began to be observed, but also by whom. Thus, it appeared that in 56% of cases the initial observation was made at least 2 years before the attack and in 29% between 1-2 years. Only in 2%, it was observed the week before the attack. Also in 87% of the cases, the deviant behavior was observed by the perpetrator's partner, in 68% by another family member, while among the perpetrators who were students in 92% of the cases the person who perceived some kind of behavior change was a classmate and in 75% a teacher.

Another particularly interesting finding was the fact that the majority of perpetrators (79%) appear to have been exposed to a mass shooting event in response to an injustice they experienced or believed they were experiencing. The reason for this feeling (injustice) varies from case to case, with the most common causes being injustice at the interpersonal level (33%) and in the work environment (16%). The fact that many people experience similar situations every day, the vast majority of whom choose to react in a non-violent way, proves that in the case of perpetrators of such attacks there is a synergy between various motives. Although in almost 4/5 of the cases the perpetrator was affected by some kind of injustice, the manifestation of the attack did not happen with the same percentages against the “target” people. This, according to the study, accounted for about 64% of cases (in 27% the victims that got murdered were pre-selected and in the rest 37% there were both pre-selected and random victims), while in about 37% of cases the victims were either completely unknown to the perpetrator, or known, without, however, being linked to his "complaints". This is explained by the fact that many times the perpetrator tries to act against a specific organization, such as a company, a school, etc. and not against specific people.

Another element of the study that could also be used in the field of prevention, is the fact that about half of the perpetrators of such attacks had committed suicide, several of whom had even attempted suicide within the year before the attack. If we exclude the cases in which, due to lack of sufficient evidence, the perpetrators were not registered in either of the two categories (suicidal ideation or not) then the percentage of those who had such behaviors is 85%.

In trying to outline the profile of a future perpetrator, it is also worth noting that more than half of the perpetrators (55%) had, to some extent, made their intentions known by making threats, mostly in person or, more rarely, in other ways such as in writing or by electronic means.

CITIZENS’ RESPOND TO MASS SHOOTING INCIDENTS

a) Before Suppression Forces intervention

It is a fact that the reaction of citizens who have been present in a mass shooting incident varies and depends on multiple factors, including the individual judgment regarding which action will better protect their lives, their characteristics, any previous education and information (or not), as well as the available means and space where the event happens [13].

However, although there is no appropriate response to all possible scenarios, specific actions have been defined to reduce casualties, the consequences of a mass shooting event, and increase survival [14].

Citizens should be aware of these guidelines to evaluate the situation and be able to react in the best possible way [15].

These instructions/guidelines, to be quite memorable, have been coded as "Run - Hide - Fight" [16, 17].

- Run

The initial instruction given to citizens is that in a mass shooting incident their first action should be to run away from the perpetrator. The move should be made to a predetermined meeting point if they are aware of it-or moving as far away from the firing point as possible until they are in a safe place. Despite the complexity of the situation, those who can move safely are advised to do so [12].

Citizens are advised to run-move, leaving behind their personal belongings so that they do not spend time and be more flexible. They should also raise their hands, making a signal to security forces that they are unarmed. Rolling stairs and elevators should be avoided. During their run-move, citizens are advised to help their fellow citizens to leave together, but not to stay behind. Finally, when citizens feel safe, it is recommended to call and inform the authorities, giving as much information as possible. The information that would be useful concerns the exact location of the incident, the number of perpetrators as well as their description, type and number of weapons or the possible use of explosives, possible number of victims, and, finally, whether shots continue to occur at the time of the call.

- Hide

If quick removal is not considered safe, the next option should be to try hiding. If possible, the place/building with the thickest walls and the fewest windows should be chosen. Doors should be locked and windows closed where possible. It would also be wise to place heavy objects/furniture behind doors. The instructions also include maintaining absolute silence from citizens who remain in hiding. For this reason, electronic devices, as well as mobile phones, should be silenced and lights should be off. As long as citizens remain hidden, they will have to consider ways to escape, looking for possible escape routes, as well as ways to deal with the perpetrators, if necessary. Attempts to communicate with authorities or with Suppression Forces should only be made when this is considered safe.

- Fight

When neither citizens’ safe removal nor their hiding is an alternative, it is recommended that citizens fight the perpetrators. According to an FBI investigation, in 17 of the 51 shooting events, the attack was stopped by civilians who were at the scene. Citizens may try to deal with the perpetrators mainly by throwing objects at them or using improvised weapons. In these cases, the energy must be as aggressive as possible. Naturally, trained individuals, such as security personnel, military, self-defense technicians, or professionals who may carry a weapon (eg security guards) are more likely to be able to deal with the perpetrator.

b) After Suppression Forces interference

A mass shooting event can take place long after the Suppression Forces have reached the scene. At this time, citizens must, on the one hand, remain as safe as possible and, on the other hand, not obstruct the work of authorities [13]. For this reason, citizens should try to stay calm and follow the instructions of the security forces. They should have their hands up and avoid screaming. This will help them to be easily distinguished from the suspects/perpetrators. Citizens should also move in the direction indicated, lying on the ground and generally being as cooperative and obedient as possible. Finally, it is useful that citizens provide relevant information that will facilitate the work of the Suppression Forces. Citizens will have to show similar behavior, remaining calm and following the instructions they receive, even after the attack has passed. This will help to better deal with the injured, identify/record the victims and not to alter the information required to investigate the incident and locate the perpetrators.

Apart from the widely used "Run - Hide - Fight" guideline, there are many other similar guidelines/instructions, also standardized in a way that is easy to remember that are proposed. One such is the "Avoid - Deny - Defend" [17-19]. This has to do with the directive, a) avoid danger (either by acknowledging the threat before the attack occurs, or moving away, b) deny access (preventing the perpetrator from accessing a safe place, if possible), c) take action (as a last resort, defending your life in any way possible by dealing with the perpetrator).

A similar process of four steps coded as "4As" also aims to reduce casualties in a mass shooting incident [20]. These steps are:
Accept: Accept that an emergency occurs
Assess: Evaluate what you need to do to increase your chances of survival
Act: take action following the "Run - Hide - Fight" direction
Alert: alert the Suppression Forces

Finally, the “ALICE” direction [21-23] is a five-step acronym that also aims to increase survival in such events:
Alert: be alert
Lockdown: if you decide not to try to escape, stay in a locked-secure area
Inform: if possible, forward the information to the authorities
Counter: If there is no other option, deal with the perpetrator
Evacuate: get away from the danger zone as soon as possible

It seems that the latest direction may be confusing, as the range of actions proposed is not in line with the rest and especially with the "Run - Hide - Fight" guideline, which has now been established as the optimal instruction for citizens to mass shooting events.

SUPPRESSION FORCES: FIRST RESPONDERS

The actions of the scene first responders are of utmost importance in a mass shooting incident [24, 25]. The first respondents are involved in both managing the incident and providing care to the injured [26]. The term "first responder" does not imply an official certification, restriction, or ability. If the attending citizens who may attempt to be involved are excluded, the first respondents are the first officials arrived at the scene and could be the police, military, firefighters, or even emergency medical personnel.

Moving on to the incident area, the first responder should ask for as much information as possible from the agency available (usually police). This information will allow access to the incident area from the safest and most convenient route, as well as the closest possible approach to perpetrators. In case that the first respondent does not have the authority to enforce order, he/she must remain safe and make an immediate request to the competent authority. Upon arrival at the scene, from the information already collected and the first scene assessment, first officials will identify the danger zone and install a point as an administration area. Depending on his training and the characteristics of the case, such as the number of perpetrators or the time needed to receive advanced help, the first responder will decide whether to operate on his own (or with the existing forces) or will wait for reinforcements to deal with the perpetrators. The first correspondent automatically undertakes the management of the incident (Incident Commander-IC) [27,28]. IC’s purpose is to develop a plan to deal with the incident based on the personnel and resources available, as well as to seek resources for the best response to the demands of the situation [29]. The first responder’s primary purpose is to stop the perpetrator, so even though he/she may assist in removing survivors outside the danger zone, IC should not be involved in helping injured people at this stage. Finally, the first responder should transmit, as soon as possible, all the information gathered to be used by the Forces that will be called to assist.

When additional Forces arrive in the incident area, they must contact the first correspondent who will have taken on the role of IC. As long as the mass shooting incident persists and the perpetrator has not been neutralized, all forces will work together IC’s common plan and guidelines to deal with [30].

As soon as the danger passes, all forces should assist the injured by applying the techniques and instructions mentioned below.

It should be noted that both IC and Command Post (the point where the administration is exercised) may change as the incident progresses. Once Suppression Forces have arrived and have started operating at the scene, the IC is usually the superior authorized officer. However, IC may be the most experienced or may be determined by other criteria, but in any case, IC should always be clearly defined to the forces involved.

Accordingly, the Command Post should be installed in a place known to all, which can be relocated, if necessary.

So that the main purpose of managing a mass shooting incident (which is minimizing casualties) be served, the incident scene is divided into three zones [31]. Within each of them, there is a different regime of security, accessibility, and actions that can take place. The direct intervention Forces must be aware of the characteristics of these three zones, while the determination of the zones should be clear to all the people involved. As a mass shooting incident is a dynamic situation, the boundaries of these zones may change over time.

- Hot zone

It is the area where there is still a risk of gunfire. Neither medical personnel nor Fire Service personnel (except for specially trained units) are not allowed to enter this zone because their entry would endanger their lives or the lives of others. Also, they may obstruct Suppression Forces' efforts, whose personnel are the only ones authorized to enter and operate in this zone, following IC's plan and instruction.

- Warm zone

It is the area where there is no immediate risk of gunfire, however, it cannot be characterized as a safe area. This implies specific restrictions on both entering the area and operating actions. Firefighters and medical/paramedic personnel may enter under IC's permission for only critical and extremely necessary actions. Medical/paramedic personnel, for example, will only participate in vital operation (life-threatening situations) to save injured people's lives [32]. The point of entry and exit as well as the possible assistance by Security Forces will also be determined by the IC. If allowed, there must be certification and registration of the people entering the warm zone. The time spent in the zone should be the minimum necessary.

- Cold Zone

This area is considered safe, without the risk of a shooting. Access is free for all emergency forces as well as their length of stay. Healthcare personnel can provide any kind of medical care required, operating based on purely medical criteria, having ensured their safety [33].

NOT ADVANCED MEDICAL CARE PROVISION

The experience of dealing with the injured during the US military operations, formerly in Vietnam and later in Iraq and Afghanistan [33], combined with similar medical research on wound care, has led to a large percentage in the establishment of modern procedures – instructions, regarding gunshot wound management. Particular emphasis has been given to tackling life-threatening active external bleeding.

The experience of war injuries in the late 1990s led to the standardization of a series of wound care procedures on the battlefield, called Tactical Combat Casualty Care (TCCC), focusing on the most common causes of death that could be treated infield, even by medical staff with no special skills [34].

Recognizing how this military experience could be useful and applicable to non-military operations, an independent group of citizens set up a Committee in 2011 (Committee for Tactical Emergency Casualty Care, C-TECC) [35]. The purpose of the Commission was to develop guidelines that would adapt the battlefield military experience to similar situations in an urban environment, taking into account the differences and peculiarities between the two operational applications [36].

In 2013, a group of Public Institutions, including police, Fire Department, the Army, Medical Institutions, pre-hospital care, etc. was convened (known as Hanford Consensus) [37,38] and the result was a consensus regarding strategies to increase survival in mass shooting events. The Committee developed the following acronym "THREAT", to standardize the process:

- **T**reat suppression
- **H**emorrhage control
- **R**apid **E**xtrication to safety
- **A**ssessment by medical providers
- **T**ransport to definitive care

The Committee argues that survivors of such an incident or the slightly injured may act as potential rescuers by following the instructions above. The Committee also considers that the control of active external bleeding should be a key skill of all the personnel of the Security and Emergency Forces. This training concerns, on the one hand, the use of a tourniquet [39] and, on the other hand, the placement of hemostatic gauzes and hemostatic agents in places when it is not possible to place a tourniquet [40].

Some of the TCCC-TECC skills that apply to mass shooting injuries in urban environments and that could also be applied by trained personnel of the Security Forces [41] to increase survival rates are:

- Use of a nasopharyngeal airway for injuries without maxillofacial trauma
- Placing the unconscious injured person in a prone position, in case of facial injury or airway bleeding
- Spinal immobilization for people with blunt trauma
- Ensuring an intravenous or intraosseous line for fluid management

ADVANCED MEDICAL CARE PROVISION

Gunshot wounds [10] can be quite deadly and therefore the most immediate medical care possible is vital to increasing victims' survival. The usefulness of an immediate intervention of specialized health care providers comes into contrast with the necessity for non-exposure of such personnel to danger. However, weighing the situation data each time, the general rule is to provide as much care as possible to the injured, while ensuring health personnel safety. At this point, the determination of action zones in the event scene is proved quite useful and crucial, since the provision of specialized health care begins before the perpetrators are even neutralized and the threat is completely stopped [42].

Healthcare providers should also follow the guidelines set out in Harvard Consensus [36, 38] and are concentrated in the THREAT algorithm. The medical care system can be divided into:

- Direct threat care: providing care while shooting or under adverse conditions
- Indirect threat care: providing care while the threat has been suppressed, but may reappear at any time
- Evacuation: providing care during the evacuation from the incident scene

The first line of care takes place within the hot zone. However, the entry of health personnel into this zone is only allowed under certain conditions. Providing care in the hot zone is restricted to only limited manipulations such as airway management and controlling active external bleeding by placing a tourniquet or applying pressure to the appropriate points. It also includes verbal instructions to victims to take care of themselves or others, if possible.

The second line of care is evolving in the warm zone [43], where the immediate threat has been suppressed for the time being and consequently, the health personnel may proceed with more invasive operations, without worrying about their personal safety, but also without complacency. In this zone, health care providers will provide advanced medical support aimed at maintaining life and stabilizing the injured before being transferred. Operations that take place at the warm zone may be: ensuring the airway access even in an invasive way, controlling bleeding using (except for tourniquet) hemostatic gauzes and agents, stabilizing fractures, as well providing fluids or blood factors (usually not at pre-hospital level), treating pneumothorax and, finally, preventing or treating hypothermia [44].

The final line of care takes place in the cold zone. This area is considered safe and has access to all health personnel involved in the incident. The priorities regarding the treatment of the injured remain the same, but there is the possibility of using additional means to achieve them. In this zone, the network for transporting the injured to the appropriate structures for the advanced medical care provider will also be established.

The limited resources available concerning the number of people that need medical support is a quite likely scenario in mass shooting incidents [45]. This may create the need for a screening system for the medical care process (triage) [42, 46]. "Triage" is defined as the process of separating the injured based on the need for immediate medical support, taking into account the possibility of benefiting from it. The triage process is applied when the needs for medical care exceed the available resources and aims to maximize the number of survivors. In other words, it aims to offer the greatest benefit to the largest number of victims with the resources available.

From time to time, various triage systems have been proposed, none has been universally accepted so far. In the case of gunshot wounds, the challenges for an effective triage system are even greater. These have to do with the nature of these injuries, where superficial injuries with minimal obvious bleeding may obscure extensive internal bleeding, and conversely, severe superficial injuries may not always indicate internal organ damage of similar severity [45].

Despite limitations, a widely used triage system, which has occasionally been used in mass shooting events, is the START system (Simple Triage And Rapid Treatment). It is a system developed in 1983 by the Fire Services and the Hoag Hospital personnel in California, and modified in 1996 [47]. Using a simple algorithm (RPM: 30-2-Can Do) evaluates respiration (Respiration, respiratory rate), circulation (Perfusion, capillary refilling time - in the presence of a radial pulse), and the level of consciousness (Mental status, execution of simple commands) [48]. Depending on the abovementioned criteria, the injured are classified into four categories:

- Immediate (marked in red): they are the injured who require immediate medical support at the scene
- Delayed (marked in yellow): refers to less serious trauma patients whose lives are not directly threatened and who require medical treatment, but not immediately
- Minor (marked in green): they are the least wounded with injuries that are not life-threatening and may be treated when possible
- Deceased/Expectant (marked in black): refers to the dead and those who have fatal injuries whose condition is considered irreversible

The triage process with the START system allows during sorting, the intervention only with simple maneuvers to open airway (jaw thrust, Tilt-chin lift) and applying pressure at the site of an active external hemorrhage [49]. The great advantage of this system is that it is relatively simple so that it can be used by properly trained non-medical staff. On the contrary, one of its disadvantages is that it usually leads to “over triage” [50].

The triage system and the injured classification will determine the priority of transfer. A key factor in the injured person transfer is time and the avoidance of unnecessary delays in assisting in the field [51]. However, at the same time, it is important to choose the destination (hospital-trauma center) that the injured should be transferred, a decision that should be made by the field healthcare providers. In cases where there is more than one possible option, the best one should be decided, taking into account both the health condition of the injured and the distance (and therefore the time) of the possible destinations, as well as the facilities of the various Health Institutions.

TRANSFER TO HOSPITAL

When a hospital’s emergency department is notified to receive victims of a mass shooting incident, appropriate preparatory actions must be taken immediately [52-54]. These actions would best be included in a pre-existing protocol for such cases [55]. The key to the best response to such events is the mobilization and recall of staff (especially doctors of surgical specialties, staff from the emergency department, operating room (OR) and laboratory personnel), informing the blood bank, providing the emergency department with crucial materials from hospital’s warehouses, as well as, decongesting the emergency department and OR, as possible [56].

Regarding the care of the wounded, initially, if needed (e.g. non-sufficient resources available) a triage procedure is also applied. At this point, there are again various triage systems, without any common acceptance. The Triage Revised Trauma Score [57, 58], even though is used mainly in a pre-hospital environment to determine the priority of injured that should be transported to a hospital/trauma center, may also be used when the injured arrive at the hospital in order to be reassessed. The parameters evaluated are the Glasgow Coma Scale, systolic blood pressure, and the respiratory rate. Depending on the score, each injured person can be categorized into one of four categories (again marked in the same colors as in the START system) which indicates the priority in terms of the need for medical care [59]

As for the injury types, the most common life-threatening situation is blood loss (active bleeding) [60]. For this reason, in case of trauma, the classic ABC life support algorithm (Airway - Breathing - Circulation) is converted to CBA, giving priority to hypovolemic shock treatment [61,62]. The need for blood, (or blood derivatives/substitutes) are expected to be high in a mass shooting incident with several injured. In the emergency department, regular assessment of the wounded should be made in order to adjust their priority. Finally, analgesia should not be omitted [63], including the trauma patients with low priority due to prior control of their bleeding by placing a tourniquet, as a significant degree of pain is expected approximately 15-20 minutes after its application [64].

In the hospital, the need for psychological assistance should not be skipped [65]. Psychological support will also be needed both to the relatives of the victims and the staff who will be in charge of dealing with a very difficult, demanding, and particularly stressful situation [66].

CONCLUSIONS

Although a mass shooting incident can occur anywhere and anytime, its prevention and deterrence must be pursued. Analyzing the perpetrator’s characteristics, it seems that, despite their great diversity, in many cases, there are precursors that can be detected. The alertness of both citizens and organizations/structures may lead to early detection of potential perpetrators and thereby averting a mass shooting incident. It turns out that it is essential citizens be informed about the best way to react to a mass shooting event. All citizens should be aware of the steps they need to take to improve their chances of survival. The "Run - Hide - Fight" directive is the most appropriate.

To achieve increased survival and a reduced number of casualties from a mass shooting event it is vital proper education be present at all levels. Security personnel must be trained in how to act in such an event. Security personnel should be trained in basic life support (first aid) and trauma skills, neutralizing the threat, and ensuring the staff's safety.

Healthcare personnel, especially those serving in crucial positions, such as pre-hospital life support and Emergency Department personnel, should also receive appropriate training. This training should include trauma management skills, knowledge about the recent guidelines, as well as familiarity with the relevant equipment. It would be useful that the critical healthcare personnel would be appropriately certificated, obtaining the required training/education to be considered suitable for involvement in a mass shooting incident.

Ordinary citizens should not be excluded from training/education. Educational programs can take place both in workplaces and in structures such as schools, places of worship, municipalities, public organizations.

The administration of a mass shooting event by the Incident Commander seems to be the most effective way to manage such an incident. For this reason, all those involved in a mass shooting incident should be aware of this management model and act accordingly.

In a mass shooting incident, the need for medical care may exceed the available resources. In this case, a triage process is needed. All emergency medical personnel should be trained in the triage process, as well as, a specific triage system has been pre-determined to achieve the best possible coordination and communication among all medical care providers involved.

The response to a mass shooting event should be imprinted in an Emergency plan. Such a plan should have been decided and made, by the Security and Suppression Forces, the Healthcare Institutions, and the Public Safety Answering Point (e.g 9-1-1). These operational plans must be updated regularly and adapted to the new data of each organization involved, by the time they are changed. All personnel involved in such an event should be aware of these plans. Ideally, the various stakeholders involved in a mass shooting event should have already worked together to draw up the plans, so that there is a clear division of roles and responsibilities, as well as common terminology and language of communication. Finally, at regular intervals, exercises should be carried out on these plans all the stakeholders become familiar with their implementation, as well as possible shortcomings/weaknesses may be identified and improve their completeness and effectiveness.

Media, medical intelligence and hybrid war

Oana M. Ciobanu[1]

Abstract: *Contemporary hybrid war is a novelty in that it is taken to populated conflict zones, with the participation of the population, under the eyes of the international community. Thus, according to many authors, the most serious threats to the United States, including to its NATO dimension and to its partnership with Europe, would come from extremist groups and their ideology, fueled by poor urban areas of the world, where youth faces great economic and social problems, and is militating for a change. These unconventional actors can operate beyond state control by circumventing international borders, norms and agreements. Some of these belong to global terrorist networks, and others co-operate with criminal elements to destabilize certain areas. The hybrid confrontation with these groups will become "a clash beyond the physical elements of the conflict, in which media manipulation, the use of the internet and the integration of information operations with strategic communication programs are as important as weapon systems on the battlefield."*

Crises generated in the context of a hybrid war are events characterized by low probability and important consequences that threaten an organization for its most profound purposes. Because of their low probability, these events defy any interpretation and require a sustained effort to understand and adapt the reactions. Crises affecting social groups differ in their causes and duration. Obviously, because of the multitude of types of crises, human reason can only play a limited role in their development. However, they trigger human action, which can turn small deviations into major crises.

Crisis and conflict management involves very complex systems of political, diplomatic, social, economic, cultural, international, military and other actions.

Such a system could be structured on political, diplomatic, social, economic, informational, military, psychological and cultural components and could include the following types of action: on the causes; on effects; on the phenomenon; on value systems; on crisis-generating strongpoints (critical areas); on vulnerable sites; on the leaders.

METHODS

The analysis of open sources of information and of the experience gained during the activity in the field of communication and public relations, concretized through the elaboration and implementation of both the communication management strategies and of the projects included in the field of defense and national security.

In hybrid war, opponents (states, state-supported or independent movements) will exploit access to modern military capabilities and support insurgent, terrorist and criminal movements as well as the intervention of states that can combine high-tech military capabilities with terrorist actions and cyberwar operations against financial targets.

The analysis of available sour-

[1] Carol Davila University of Medicine and Pharmacy, Bucharest

ces suggests that the likelihood of a hybrid warfare is in direct connection with local population's satisfaction and the stability of states. Experts believe that, in failed or failing states, population security and services are often provided by dissident groups, armed factions, and criminal gangs. These areas become a fertile ground for terrorist, fundamentalist, extremist groups with regional or global influence and seriously affect the world economic system by facilitating illegal activities.

Contemporary hybrid war is a novelty in that it is taken to populated conflict zones, with the participation of the population, under the eyes of the international community. Thus, according to many authors, the most serious threats to the United States, including to its NATO dimension and to its partnership with Europe, would come from extremist groups and their ideology, fueled by poor urban areas of the world, where youth faces great economic and social problems, and is militating for a change. These unconventional actors can operate beyond state control by circumventing international borders, norms and agreements. Some of these belong to global terrorist networks, and others co-operate with criminal elements to destabilize certain areas. The hybrid confrontation with these groups will become "a clash beyond the physical elements of the conflict, in which media manipulation, the use of the internet and the integration of information operations with strategic communication programs are as important as weapon systems on the battlefield."

The issue emerging in the hybrid war resides in the fact that the enemy is trying to circumvent the military victory by focusing on long-term political victory by encouraging and maintaining tensions, crises and conflicts on a small scale, with implications at regional and sub-regional level, using the media handling concept with increasing intensity. Almost every person has come to have their own perception about manipulation, but without a complete conscious understanding of its content.

In the public debate, confusion is often made between information, adhesion, influence and manipulation.

Through the means of mass communication, the meaning of the war creates, metaphorically, a war of the meaning, of information, that conveys and / or prevents opponents from accessing information to influence their emotions, motives or goals, aiming at obtaining behaviors and actions favoring initiators.

The influencing action – whether by coercive or non-coercive strategies – has the purpose of altering the behavior of the people it is exercising upon. Regardless of the type of influence exerted on the individual, it produces its effects only through the human psyche.

In other words, any action of influence on an individual – be it propaganda, threat, promise, persuasion, intimidation, blackmail, noise, annoyance, surprise or harassment, etc. – it achieves its effects through the human psyche.

All definitions given to communication, regardless of the schools of thought to which they belong or the guidelines they enclose, present at least the following common elements: communication is the process of transmitting information, ideas, opinions, opinions from one individual to another, or from one group to another; conscious communication is an attribute of the human species; activities, events, processes and decisions involving people cannot be conceived beyond communication.

Any communication process has the following components (Zorlentan, T., 2001): Issuer; Receiver; Message; Context; Communication channels. An efficient communication process calls for both categories of channels to be considered, knowledge of how they operate, and the benefits and drawbacks that exist in their use and control [1].

Any human behavior, however, cannot be determined directly, but indirectly by actions on the elements that determine its appearance.

Misinformation consists of any intervention on the basic elements of a communicative process that deliberately modifies the messages being circulated in order to trigger in the target groups certain attitudes, reactions, actions desired by the opponent.

Vladimir Volkoff [2] defines misinformation as a "manipulation of public opinion for political purposes, using information subjected to hijacked means", as well as several ways in which it could be used: discrediting; undermining leaders' reputation; ridiculing traditions.

He also sets out twelve ways of effectively using misinformation to change the attitude of public opinion and to force it to act in the proposed direction of the manipulators: denial of deeds; reversing the facts; the mixture of truth and lies; changing the motif; changing circumstances; blurring; camouflage; interpretation; generalization; illustra-tion; unequal parts; equal parts. [3]

Disinformation as a weapon carefully conceals its origin and camouflages its intention of transforming the target into a manipulated object, refusing its right to specific traits and behaviors.

"Manipulation is the action of determining a social actor (person, group, community) to think and act in a way that is compatible with the interests of the initiator, instead of his interests, by using persuasion techniques that deliberately distort the truth, leaving the impression of freedom of thought and decision (...) The true intentions of the person who conveys the message remain insidious to the recipient. From a political point of view, manipulation is a form of imposing the interests of this class, group, community, not by means of coercion, power, but by ideological ones, by deception." [4]

In defining the notion of manipulation, it is necessary to specify a few specific elements [5]:

- The dissemination of a large amount of detailed information that cannot be verified while also concealing the real aspects of a case;

- The obsessive repetition of information with a negative trend, to be fixed in the memory of the listeners;

- <embargo> on the real information;

- Exploiting the fact that people are hungry with rumors.

New information technologies often separate the information as such from the identity of the person who initiated the news, and thus from the particular social context that would give it a certain credibility and a certain meaning. From this point of view, the power is directed towards credible communicators, towards those who can also offer a frame in an understandable context, easily recognizable by public opinion.

The context in which the news is located is very important – the reputation and credibility of the communicator matters. Type/brand becomes extremely important as a result. If 50 years ago, the battle was to gain control over the means of transmitting information, today the battle is being done to build/destroy credibility. The illusion of the need for information to be provided "readily interpreted" has been created, that is why the credibility of the source is a guarantee of a good interpretation. Global transparency, driven by new media opportunities and low-priced technologies, is now setting the stage for media outreach.

Thus, it is necessary to communicate very clearly to the target which will be its personal benefit by adopting a certain behavior or attitude, instead of the national, pan-national or regional benefit it will receive. The promised benefit in the future for that person must be personalized.

As for the brand image (it can be, for example, the US one), particular attention should be paid to the five basic dimensions of a brand: presence; relevance; differentiation; credibility; image and target. [6,7]

Crises are events characterized by low probability and important consequences that threaten an organization in its most profound purposes. Because of their low probability, these events defy any interpretation and require a sustained effort to understand and adapt reactions.

As a consequence, we can state that the crisis is an acute phenomenon which, left uncontrolled, can become chronical – that is, it can degenerate into conflict, therefore the dynamics of the decision-making process is particularly complex and it is carried out in most situations under uncertainty and stress.

Analyzing the phenomenon of crisis, we express the opinion that any crisis of any nature, has certain characteristics, such as: Threat; Expedite; Surprise; Time pressure; increased uncertainty and intensity.

Crisis and conflict management involves very complex systems of political, diplomatic, social, economic, cultural, international, military and other actions.

Such a system could be structured on political, diplomatic, social, economic, informational, military, psychological and cultural components and could include the following types of action: on the causes; on effects; on the phenomenon; on value systems; on crisis-generating strongpoints (critical areas); on vulnerable sites; on the leaders

Case Study: Ebola, Romania, 2015 [8]

The hypothesis of biological warfare, using the hemorrhagic fever virus, Ebola, as a weapon, was brought to the attention of the specialized public by military intelligence analysts, but also by the medical academics.

Although insignificant in size and proportions, the media crisis caused by the presence of Ebola virus in Romania raised concern at the level of state structures actively involved in the early detection, isolation and treatment of these patients, which led to the development of an action and communication strategy, following the premises mentioned in this article, which has also been concretized through an evaluation mission of the European Union experts.

Thus, during March 19-21, 2015, at the invitation of Dr. Raed Arafat, State Secretary and Head of the Emergency Situations Department of the Ministry of Internal Affairs, an expert team led by ECDC visited Romania. The main objectives of the visit were to provide specialized support to public institutions with tasks and responsibilities in the field of health, in order to review and verify the effectiveness of operational emergency intervention procedures, to verify the mechanisms of national inter-institutional cooperation in the context of management, under maximum safety and security conditions, of the cases imported by Ebola.

The main finding of the report was that Romania took the threat of Ebola seriously and initiated and established a wide range of measures as soon as possible, being able to ensure the rapid detection of infected persons, transport and specialized medical care, under conditions of maximum security for the staff involved in this procedural chain. Immediately after the World Health Organization Statement of October 2014 disclosing the threat to the Ebola virus, which was categorized as an emergency of international public health, the National Emergency Situation Committee of Romania created a national network, dedicated to managing this threat.

The role of the Ebola National Committee is to coordinate the interventions and measures needed to prevent and combat Ebola virus infections. It is chaired by the Head of the Department for Emergency Situations (Secretary of State within the Ministry of Internal Affairs), Vice-President - Secretary of State within the Ministry of Health.

In the Committee there are governmental decision making actors, namely within the Ministry of Health, the Ministry of Internal Affairs (Department for Emergency Situations), the Ministry of Foreign Affairs, the Ministry of National Defense, the Ministry of Education and Research, the Ministry of Transport, as well as key institutions, subordinated to these ministries, such as the Public Health Institute, the National Institute of Infectious Diseases "Matei Balş" and the Central Military Hospital "Dr. Carol Davila".

Throughout this period, the Ebola National Committee has worked intensively to develop a coherent national strategy for preparing for the safe identification and management of possible cases of Ebola and has consequently adopted seven decisions in this area, covering various issues related to early detection, triage, management and prevention of future spread of the Ebola hemorrhagic fever virus, as well as the creation of a dedicated budget to support this activity.

According to the Report, public health activity at the local level is carried out at the level of 42 public health authorities (VATA), and centralized data are provided to the National Public Health Institute (NPHI), which works under the aegis of the Ministry of Health. The Institute has five branches in the main cities:

Timişoara, Iaşi, Cluj-Napoca, Târgu-Mureş and Sibiu, and monitors all epidemiological situations with potential for national and international impact, along with other relevant institutions, being involved in activities aimed at increasing the degree of awareness. The site of the institute is the most complete and complex source of information, updated for both professionals and the general public. Although not mentioned in the Ebola National Committee's decisions, the NPHI also has the role of conducting and implementing population training campaigns, while maintaining institutional dialogue with regional public health authorities (VATA) as regards the evolution of relevant epidemiological issues, as well as contributing to the training and professional development of public health specialists.

In addition, CNAS and the Ministry of Health provide the early warning and response system to threats to national and, implicitly, European health security, assuming its responsibilities and commitments to WHO to address issues related to the implementation of the International Health Regulation (IHR).

At European level, key actors from other sectors of activity (e.g.: international affairs, civil protection, etc.) have been actively involved in discussions and in the start of inter-sector collaboration protocols that have taken place. In addition, a number of EU/EEA Member States have extensively participated in international efforts to counter the African epidemic by providing expertise, logistical and financial support.

Although for many countries the danger has passed, some European countries may still be at risk of exposure to the Ebola threat, given the migration phenomenon of residents from countries on the African continent, especially those in the West, severely affected by this disease.

The EU Health Security Committee continues to work to ensure effective communication at Member State level, in particular as regards the development and establishment of a joint action plan of addressing this challenge, further enhancing the dimension of the concept of preventing the spread of the disease by examining cross-sectoral and cross-border issues, as well as by checking capacities and capabilities for responding to biological incidents and accidents with extremely violent public health impact.

The lessons learned by Romania in this context have brought back a number of issues on the public agenda, such as the fragility of the healthcare and public health infrastructure; the high exposure to infection, given that our country is a gateway to Europe for the African population.

National vulnerabilities: lack of specialized medical personnel (in 2007 out of a total of 45 000 doctors, only 16 000 remained in Romania, others preferring other Member States, the phenomenon of labor migration is acutely felt in the intensive care, epidemiology and infectious diseases departments), the management of bio-waste, the lack of joint training drills in case of biological danger, the possible difficulties in the organization of medical evacuation - at this moment in Romania, there is no generic preparedness plan for a rapid response to eradication of outbreaks of infectious diseases, although it would be relatively easy to establish one as a result of the Pandemic Influenza Preparedness Plan used during 2009-2010-, the blocking of public procurement for advanced products/devices to support activities in the medical field as well as research-innovation and health system development.

An important aspect is also the need to ensure the functionality of a public health lab, of vital importance both for the national preparedness to respond to the threat of infectious diseases and for mandatory reporting at EU level through the ECDC. Not even today did the analyzes carried out by the Ion Cantacuzino National Research and Development Institute for Microbiology and Immunology surpass the threat of the uncertainty of activity financing, a key component of the public health system, which entails a whole chain of vulnerabilities that converge significantly to creating a state of health insecurity.

CONCLUSIONS

That is why medical intelligence, defined in Joint Pub 1-02 as "a type of information products resulting from the collection, evaluation, analysis and interpretation of medical, biological and scientific data as well as from the climate-related data, represent a special category, essential to national strategic planning, whether we are talking about the military or civilian environment, the planning of the fighting force conservation operations or the performance of medical capabilities assessments of rapid intervention."

"The role of medical intelligence structures is often confused with that of preventive medicine. Although the two disciplines have no common ground, they have become complementary over time, even in a relationship of interdependence.

While preventive medicine attempts to identify those events that constitute medical threats to subsequently assess the risks posed by exposure to such threats, while ensuring at the same time that decision-makers are advised on the adoption of preventive strategies, the medical intelligence is the component which ensures the permanent upgrading of the prevention process by identifying new types of non-conventional medical risks and threats, described in the published literature, in the possession of potential aggressors, depending on the changes in the security climate and the geostrategic map of influence (state actors or terrorist militarized formations), assesses new trends and medical technologies, especially in the dual-use industry." Medical causes and diseases leading to early permanent disqualification in IRIAF pilots based on their service categories

Mohammad Darvishi[1], Hamze Shahali[1]

Abstract: *Background and Aim: Efficient manpower is the most important capital and studies have shown the relationship between health and performance.Understanding the factors leading to disability has preventive importance.Our aim is determine the causes and diseases leading to early permanent medical disqualification of the Islamic Republic of Iran Air Force pilots based on their service categories.*

Methods: This is a descriptive, cross-sectional, retrospective study with target population of the Islamic Republic of Iran Air Force pilots with early and permanent medical disqualification from 1986 to 2016.

Results: Out of 508 cases of early medical discharges, 239 items were considered medical disqualification, 17 war captives, 34 service exchange and the remaining 218 was for on service killed or missed persons.The main medical causes were neurosurgery, cardiovascular and psychiatric, while common diseases include lumbar discopathy, myocardial infarction and cardiac arrhythmia.The lost service years was 3233 person year and the average was 12.63 person year per individual.

Conclusions: Based on the previous similar studies, it was expected that the common cause include neurosurgery, cardivascular and psychiatric with more prevalence in fighter, transportation, and helicopter service categories.At the end, we found that our results were in line with initial expectations.

Keywords: *disabilities, medical disqualification, health, prevention, performance*

INTRODUCTION

Human resources are the most important capital of armed forces, and many studies have shown the strong links between personal health and organizational performance. In order to increase productivity, organizations have adopted numerous measures not only to evaluate pre-employment health status, but also monitor staff health during their service life. Nonetheless, health risks remain the most important reducing factor of personal productivity. Disability is defined as the effect of a disorder on physical, mental, and social activity of a person where the work environment and the family status are also effective elements [1, 2, 3, 4]. According to statistics, effective prevention of cardiovascular risk factors in aviation population has a significant role in improving the professional health index of aviators (pilots). The study of aviator’s work environment and their lifestyle, active intervention, periodic regular examinations and screening tests for early detection of diseases are among the basic measures [10].

These days, the economic, mental and social problems caused by disability in armed forces are critical burdens. Regardless of the huge cost to run and maintain a powerful army, the supportive burden of victims can be devastating for any society [22]. In 1993, the United States (U.S) army paid 500 million dollars to compensation newly recruited armed forces [7, 8] In a study between 1980 and 1994 on the

Corresponding author: Hamze Shahali
hamze.shahali@ajaums.ac.ir

[1] Aerospace and Sub-Aquatic Medical Faculty, Aja University of Medical Sciences, Tehran, Iran

causes of disability in U.S. air and sea forces, it has been shown that disability in armed forces had led to an excessive cost of about 1.5 billion dollar in form of a compensation [2].

The preparation of military pilot volunteers to enter professional trainings and the provision of optimal services in the form of well-trained pilots require a huge amount of resources, both physical and intellectual [1]. The ultimate goal of present study was to determine the causes and diseases which led to early permanent medical disqualification (EPMD) of Islamic Republic of Iran Air Force (IRIAF) pilots based on their service categories from 1986 to 2016. Other objectives include; determine the causes and diseases which led to EPMD in IRIAF pilots who captured during the war, killed or missed in actions or have been forced to change their service category due to medical reasons, their lost service years (LSY) and its average and provision of scientific and practical solution to prevent the EPMD of IRIAF pilots, all based on their service categories.

METHODS

This is a descriptive-cross sectional-retrospective research which ethically approved by the ethics committee of the Aerospace and Sub-aquatic Medical Faculty in Aja University of Medical Sciences (with registration No# 10167118) and was conducted by the personal expenses of the corresponding author. However, like other up-to-date military articles, we are reluctant to disclose a number of military confidential information (i.e. total number of assessed cases). All the IRIAF pilots(which all are male) with EPMD who had relevant official records from 1986 to 2016 was included in the study and those who had medical disqualification due to physical or mental illness and death in non-occupational accidents, non-medical reasons, personal requests or disciplinary punishments were excluded. In this study, all pilots were captured during the war, killed or missed in actions, and those who confronted with service exchange were classified as permanent disqualification. However, this is one of the study advantages and all data was illustrated in detail separately. In order to observe the principle of confidentiality a non-disclosed random ID code were assigned for every person.

Main disease of the participants was classified based on the ICD-10 (10th version of international classification of diseases) and registered in to the Microsoft excel-based pre-designed electronic data sheet. Other recorded information included; date of entry into the service, date of departure from the service and service categories. Indeed, the total lost service years and average lost service years were calculated for each service category. Finally, this data was analyzed and displayed as graphs and figures for better presentation.

RESULTS

During the period of 1986 to 2016, 508 cases of early permanent discharges occurred in IRIAF pilots which contained; 239 medical disqualification, 218 killed or missed in actions, 34 service exchange and 17 war captives (Table 1).

Table 1: Study data

Service pilots categories / **Status**	**Fighter**	**Transportation**		**Helicopter**	**Total**
		light	**heavy**		
Medical disqualification	171	20	26	22	239
War captives	16	0	0	1	17
Killed or missed in actions	159	7	30	22	218
Service exchange	28	0	3	3	34
	374	27	59	48	508
		86			

The most prevalent medical causes of EPMD in IRIAF pilots were neurosurgery, cardiovascular and psychiatric (Figure 1).

A gynecological and urological consultation was requested for a non-functioning urethral-vesical catheter of a 60 years-old female patient admitted in the Orthopedic Department that underwent surgery with external fixation 2 days prior for a complex pelvic fracture (transverse fracture of the right acetabulum, left obturator ring fracture, left sacral fracture, fifth lumbar transverse apophysis fracture with paralysis of the external left sciatic nerve) (Figure 1).

The most common diseases led to EPMD in IRIAF pilots included; lumbar discopathy, myocardial infarction, cardiac arrhythmia, generalized anxiety disorder and post-traumatic stress disorder (Table 2).

Figure 1: Causes lead to the EPMD of IRIAF pilots based on their service categories

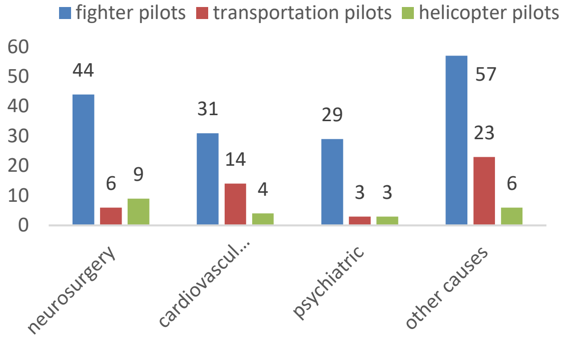

Table 2: Diseases lead to the EPMD of IRIAF pilots based on their service categories

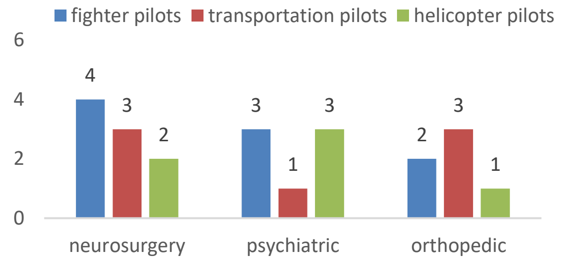
Service pilots categories Status	Fighter	Transport	Helicopter
Lumbar discopathy	18	5	5
Myocardial infarction	12	6	2
Cardiac arrhythmia	10	2	1
Generalized anxiety disorder	10	0	1
Post-traumatic stress disorder	10	0	0
Other diseases	111	33	13

The most prevalent medical causes of EPMD in war captive IRIAF pilots were neurosurgery, psychiatry and orthopedics (Figure 2).

Figure 2: Causes lead to the EPMD of war captive IRIAF pilots based on their service categories.



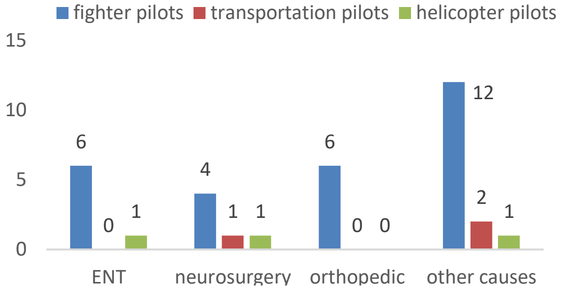
The most common diseases led to EPMD in war captive IRIAF pilots included; post-traumatic stress disorder, lumbar vertebral fracture with fusion and complicated bone fracture (Table 3).

The most prevalent medical causes of permanent medical service exchange (PMSE) in IRIAF pilots were ear, nose and throat (ENT), neurosurgery and orthopedics (Figure 3).

Table 3: Diseases lead to the EPMD of war captive IRIAF pilots based on their service categories

Service pilots categories Status	Fighter	Transport	Helicopter
Post-traumatic stress disorder	3	1	1
Lumbar vertebral fracture with fusion	2	0	1
Complicated bone fracture	1	0	1
Lumbar discopathy	1	1	0
Cervical discopathy	1	0	1
Other diseases	3	0	0

Figures 3: CT-scan showing complex pelvic fracture and the communication between the bladder and the left labia.



The most common diseases led to PMSE in IRIAF pilots included; motion sickness, complicated bone fracture, lumbar discopathy (Table 4).

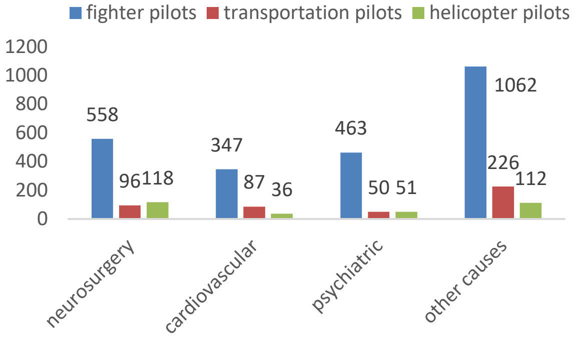
Table 4: Diseases lead to the PMSE in IRIAF pilots based on their service categories

Service pilots categories Status	Fighter	Transport	Helicopter
Motion sickness	6	0	0
Complicated bone fracture	4	0	0
Lumbar discopathy	2	1	0
Cervical discopathy	2	0	1
Generalized anxiety disorder	2	0	0
Other diseases	12	2	2

As 3233 LSY, 2457 (%76) was belong to fighter pilots, 459 (%14.4) to transportation pilots and 317 (%9.8) to helicopter pilots. The most prevalent medical causes of LSY in IRIAF pilots with EPMD were neurosurgery, psychiatry and cardivascular (Figure 4).

The most LSY in IRIAF pilots with EPMD were belong to lumbar discopathy, generalized anxiety disorder and cardiac arrhythmia (Table 5).

Figure 4: Causes lead to the most LSY in IRIAF pilots with EPMD based on their service categories.



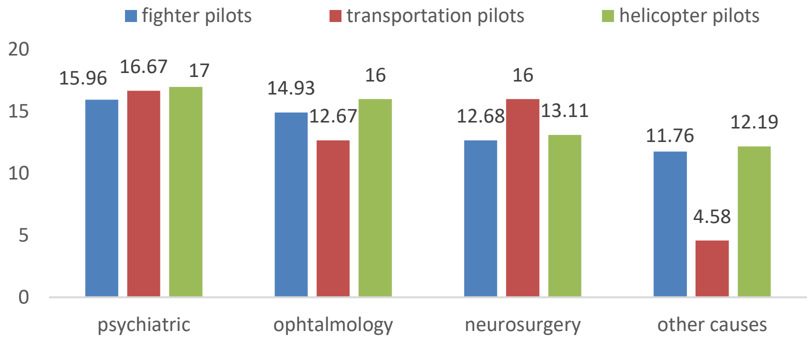
The average of LSY in IRIAF pilots with EPMD was 12.63 person year per individual (13.14 in fighter, 9.98 in transportation and 13.78 in helicopter pilots).

The most prevalent medical causes of LSY average in IRIAF pilots with EPMD were psychology, ophthalmology and neurosurgery (Figure 5).

Table 5: Diseases lead to the most LSY in IRIAF pilots with EPMD based on their service categories

Service pilots categories **Status**	**Fighter**	**Transport**	**Helicopter**
Lumbar discopathy	225	80	56
Generalized anxiety disorder	187	0	12
Cardiac arrhythmia	136	19	18
Complicated bone fracture	151	0	0
Post-traumatic stress disorder	151	0	0
Other diseases	1067	360	231

Figure 5: Causes lead to the most LSY in IRIAF pilots with EPMD based on their service categories.



The diseases resulted in the highest average of LSY in IRIAF pilots with EPMD included; migraine, cardiac arrhythmia and lumbar discopathy (Table 6).

Table 6: Diseases lead to the most LSY average in IRIAF pilots with EPMD based on their service categories

Service pilots categories **Status**	**Fighter**	**Transport**	**Helicopter**
Migraine	13	16	23
Cardiac arrhythmia	13.6	9.5	18
Lumbar discopathy	12.5	16	11.2

DISCUSSION

In the study of Whitton-1984 on United State Air Force (USAF) pilots and navigators, the common causes were cardivascular and neurologic [17], while in the same study of Mc Crary-2002, the most common causes in 1995 to 1999, include cardivascular, musculoskeletal, neurologic and endocrinology [12]. Also, in the study of Montazeri-2005, the most common causes of EPMD in IRIAF pilots included cardivascular and musculoskeletal [20]. In the study of Ghazizade-2010 on the same population in 1992 to 2003, cardivascular, nervous-skeletal and gastrointestinal were the most common causes [19].

In the study of Dark-1986 with the help of The Federal Aviation Administration (FAA), on medical disqualification of American airlines pilots in 1983 and 1984, the most commonly reported causes were cardiovascular and Neuropsychiatric events [18]. In the Nakanishi study on permanent disability of 260 Japanese crews, significant causes include malignancies, neurodegenerative, cardiovascular, gastrointestinal and musculoskeletal disorders [9]. In the review of trained pilots on Commonwealth countries from 1994 to 2004, the causes of cardiovascular were prevalent [19]. In the Arva study on 257 Norwegian civil pilots, the main causes were cardiovascular, neurologic, musculoskeletal and psychiatric disorders [11]. In the studies of Mitchell-2004 and Evan-2006 on sudden incapacitation of British civil pilots, 36 cases have been diagnosed and half of them were due to cardiovascular, cerebrovascular and psychiatric disorders [13, 14]. In the Nezami study on 200 civil pilots of Vnukovo airport in Moscow, cardivascular, neurologic and digestive have been the main causes of medical disqualification [10].

In the Mc crary's study, the more common diseases were ischemic heart diseases, high blood pressure, back pain, inter vertebral disc disorders and migraine [12]. In the study of Nezami, ischemic heart diseases, myocardial infarction, high blood pressure, cerebrovascular sclerotic lesions and peptic ulcer have been common [10]. FAA has conducted a great comprehensive study in 2014 on the causes of medical disqualification of pilots listing fifteen major causes, including; pectoris angina, bipolar mood disorder, cardiac valve replacement, coronary artery diseases, diabetes mellitus, loss of consciousness with unknown reason, seizure, cardiac replacement, myocardial infarction, permanent pace maker, disabling personal disorder, psychosis, drug abuse and dependency and lack of neural control, in order of significance [16].

In the study of Montazeri, the mean LSY of IRIAF retired with EPMD was 6.5 person year per individual [20]. In the Ghazizade study, the mean LSY was 6.14 and the highest was 10 person year per individual [19].

The present study has limitations that include: 1) missing details due to the lack of presence of a comprehensive electronic system for recording personal medical records; 2) the possibility of oriented malingering in disorders where specific objective diagnostic methods are not available and were mostly diagnosed subjectively, such as motion sickness, migraine and etc, and 3) flying device factors (ergonomics and exhaustion), operational and airbase factors (work and rest schedule), Personal factors (life style, physical and psychological capabilities, socioeconomic state, use of legal and illicit drugs and habits), medical factors (medical and psychological advices and hygiene education) are important items which have effective influence on pilots health.

The current investigation has important advantages such as: 1) so far, in terms of quantity and quality, there is a limited number of similar studies have been conducted about military pilot's health; 2) it has the longest cross-sectional period (35 years), the closest was performed during a 10-years period [18]; 3) express the statistics of IRIAF pilots which captured during the war, killed or missed in actions and those who confronted with service exchange, and 4) Records given were sorted according to the service categories.

CONCLUSIONS

More studies should be conducted on military and civil aviator's (pilots) health in the future. We believe that the life style modifications, regular fitness training, hygiene and health education and use of medical and psychological counseling for preventing the EPMD in military pilots are necessary preventive steps to take. Also, use of up-to-date comprehensive electronic system, upgrading on-the-job examinations, sufficient periodic in-service examination in occupational health centers are recommend by authors.

Medical devices in current medicine

Viorel Ordeanu[1,2], Lucia E. Ionescu[1], Victoria G. Dumitrescu[1], Roxana G. Pricop[1], Răzvan Neagu[1], Diana M. Popescu[1]

Abstract: *The treatment of diseases is based on pharmacological and non-pharmacological means, but adequate devices are needed for their application. Medicine uses a wide range of medical devices. Currently, many medical devices are used, many of them being disposable. As recognition of the importance of medical devices, the national authority of the drug is the ANMDM (National Agency for Medicines and Medical Devices).*

Medical devices are indispensable for therapy, and their evolution has led to an extraordinary diversification of the field and the emergence of industry related to the pharmaceutical industry, with specific laws and regulations.

Keywords: *medical device, medicine, pharmacological action, non-pharmacological action, health legislation*

INTRODUCTION

The treatment of diseases is based on pharmacological and non-pharmacological means, but for whose application different devices are needed, suitable physical objects, without which treatment cannot be applied. Modern medicine uses a wide range of medical devices, some derived from classical forms, and others that are new and more complex, which revolutionize therapy. Although their use is very old, the term as such has been newly introduced in medical terminology, from the English terminology medical device. Another neologism, related to this, is disposable = available, which, together with a noun, also means "disposable". Currently, many medical devices are used, either small or large, simple or complex, many of them being disposable. As a recognition of the importance of medical devices for the medical and pharmaceutical field, as well as for the medical and pharmaceutical industry, the current national authority of the medicines (not a drug, apud WHO) has been renamed the ANMDM (National Agency for Medicines and Medical Devices) [1, 2].

GENERALITIES

Definition: "Medical device" means any instrument, apparatus, machine, appliance, or other item used alone or in combination, including the software necessary for its correct application, intended by the manufacturer to be used for human beings, and which does not achieve its primary intended action by pharmacological, immunological or metabolic means, in or on the human body, but which may be assisted in its intended function by such means, for one or more of the specific medical purpose(s) of:

- diagnosis, prevention, monitoring, treatment or alleviation of the pain,
- diagnosis, monitoring, treatment, alleviation of or compensation for an injury,
- the investigation, replacement, modification, or support of

---

ionescu.lucia@gmail.com

[1] Military Medical Research Center, Bucharest, Romania
[2] "Titu Maiorescu" University, Bucharest, Romania

the anatomy or a physiological process,
- control of conception (Law 176/2000).

Legislation

The specific legislation, including regarding medical devices, also appeared later on - in 1976, the Regulatory System for the MD - US. In 1993, the EU Regulatory System 93/42/EEC and Romania: Law 176/2000 on medical devices and Law 434/2004, with the Government Decision and Orders of the Ministry of Health. Example: HM Order 253/2010 regarding the reclassification of medical devices and 75/2010 for the Rules for Good Pharmaceutical Practice.

Within the HM, operate specific structures such as the Commission for Medical Devices and the National Agency for Medicines and Medical Devices. We mention that in the European Union, the pharmaceutical field was removed from the Health and included in the Industry, which caused some controversy in the medical world [3-23].

Authorization

Medical devices can only be marketed if they are effective, meet the intended purpose, and ensure patient safety. The certificate of conformity issued by the manufacturer guarantees the attestation of the product for being placed on the market and the classification in the corresponding risk class. The inscription must comply with the European Conformity Marking "CE" (conformitè europèene), which allows free movement in the EU space and should not be confused with "C E" (China Export), which has a space between letters. It turns out that a new medical device, being a product of the scientific research of development-innovation, will go through the following stages: Experimental model, Functional experimental model, Prototype (technological demonstrator), and zero series (at the manufacturer). The technical file of a medical device, which is subject to the approval of the NAMMD, contains information regarding the: device description, type of raw materials used for manufacturing, stability study, analysis bulletin, validation, description of the packaging, and instructions for use. The serial products must be manufactured with the technical assistance of those who have the patent for the product.

CLASSIFICATION

There are many types of medical devices and they can be classified according to several criteria:

1. Risk level
- Class I, Low risk: non-invasive medical devices (eg patches, bandages) and invasive (eg surgical gloves);
- Class II, Medium risk (use 1h-30 days) invasive (eg needles, catheters);
- Class II b, potentially high risk (use - more than 30 days) invasive (eg: probes, devices for repeated administration) and non-invasive (eg: modern dressings that come in contact with the damaged skin);
- Class III, High risk: surgically invasive, a tissue of animal origin, implantable or an integral part of a drug (eg dressings with antibiotics).

2. Access path
- Urinal,
- Digestive,
- Surgical,
- Respiratory,
- Parenteral.

3. Duration of use
- Transitional action, less than 1 hour,
- Short term, less than 1 month,
- Long term, over 1 month.

4. Frequency of use
- Single-use,
- Repeated,
- Permanent,
- When necessary.

5. Impact on the body
- Non-invasive,
- Invasive,
- Surgically-invasive,
- Implantable.

6. Method of manufacture
- Sterile (disposable or re-sterilizable),
- Nonsterile/aseptic.

7. Mode of operation
- With power source (eg electric battery),
- Without a power source.

8. Place of use
- Medical institution,
- Home,
- Portable.

After use in different activities:
Medical devices for:
- Diagnosis and monitoring,
- Administration of medicines,
- Parapharmaceutical (ex: dressings),
- Damaged tissue (orthopedics, surgery, burns),
- Oral hygiene,
- Sexual protection,
- Childcare,
- Medical imaging.

Categories of users:
- Manufacturing companies,
- Suppliers and distributors,
- Sanitary units,
- Medical technical workshops,
- Patients and clients.

QUALITY

The quality requirements are set out in the specific Reference Standards. Starting with 01.03.2019, ISO 13485: 2016 is mandatory. This standard is designed for organizations involved in the design, production, installation, and maintenance of medical devices and for risk management.

• Sterility

All devices and technical-medical products that come into direct contact with tissues and biological fluids are required to be sterile.

Sterilization by heat, gas, or radiation is chosen depending on the nature of the material to be sterilized and the efficiency of sterilization is checked according to FR X unless otherwise provided.

• Storage

The storage and transport of medical devices are done according to the general provisions of FR X unless otherwise provided. Some materials must be stored under special conditions: rubber, plastics, metal tools, dressing materials, and utensils.

LABELING

Markings

Medical devices must be labeled, on the product, on the packaging and the instructions for use with the information essential to the safety of the user:
- The product's name,
- Identification of the manufacturer,
- Lot number and series, including the date,
- Storage conditions,
- Method of operation.

In some cases, additional data is required for special labeling:
- Sterile,
- Disposable,
- Exclusively for clinical investigations;

Different graphic symbols or warnings can be added.

RISK MONITORING

The safe handling of health products is called vigilance:
- Pharmacovigilance for pharmaceuticals and pharmaceutical raw materials,
- Materiovigilance for medical devices,
- Reacto-vigilance for in vitro diagnosis,
- Biovigilance for temporary-use cellular products,
- Hemovigilance for blood products.

Materiovigilance pursues the incidents arising from the use of the technical-medical products, to ensure the safety of the medical procedures, permanent monitoring of the incidents, and the risks of their occurrence. On the Materiovigilance Data Sheet are reported the essential information related to erroneous indications, omissions, or incomplete instructions. On their basis, studies and expertise are also carried out for the continuous evaluation of the risk level after being launched on the market.

RAW MATERIALS AND PACKAGING

The raw materials can be natural or artificial, single or in combinations: cellulose, cotton, metals, and alloys, natural and synthetic rubber, ceramic materials, glass, plastics, etc. or combinations thereof. All materials used must be compliant for medical use, from pharmaceuticals to the finished product, including packaging. As an example, medical devices for the application of innovative antibacterial and/or antibiofilm drugs fall within the general definition, according to the legislation in force. They must meet all the conditions for authorization, both as a package and/or applicator, and as a medicine administered for the treatment of the patient; they must come accompanied by a Technical File, Analysis Report, and a Conformity Certificate endorsed by the HM through the NAMMD. They fall into Class II b of Potentially High Risk, non-invasive as modern dressings, which are exposed to damaged skin or Class I Low risk, non-invasive. All components must be sterile or aseptic and must be stored and used properly. The labeling must be complete, accompanied by the appropriate markings and with the follow-up on the Materiovigilance. The pharmaceutical forms and the packages (applicators) in which they can be presented may differ, depending on the particularities of the treatment, being required several experimental models for choosing the prototype. Each of the components must come accompanied by a medical opinion for use, and if it does not, it must be requested from the NAMMD, which means time and money for taxes [3, 4, 9, 12].

As examples of medical devices for the application of pharmacologically active drugs may be listed the following:

1. Paper sachets, amylaceous, etc.
2. Capsules: soft or hard, gastro-soluble or gastro-resistant, with compartments or concentric (delayed), etc.
3. Pencils: liquid or powder dosage, etc.
4. Ampoules: glass or plastic, brittle, compartmentalized (lyophilized powder and solvent).
5. Bottles: glass or plastic, perforable, dropper, jet, sprayer (passive, active)
6. Bottle/dose atomizer under pressure (spray)
7. Patches: fast or delayed (for different areas) etc.
8. Implants: in an orifice, subcutaneous, submucosal, and visceral (eg: ovules, suppositories, spark plugs, cones, etc.)
9. Impregnated dressings: solutions, powders, solubles, ointments, absorbable or non-absorbable, hydrogel, etc.

COMMENTS

Currently, our research team is studying medical devices for the application of pharmacologically active drugs, for the substitute, adjuvant or complementary treatment to the anti-infective treatment, especially against resistant bacteria.

There are different medical devices, suitable for types of substances and dosages, authorized for medical use, from which we can choose the most suitable for the purpose; creating a new device, simple or complex, would require a complicated and costly procedure, but unnecessary in this case. The range of medical devices that can be filled with the appropriate pharmaceutical preparation is currently provided by the pharmaceutical industry upon request.

By combining the newly proposed drug with the chosen medical device, experimental model variants are achieved [24]. After experimenting with these under different conditions, the functional experimental model is obtained, as a masterful and/or galenic pharmaceutical preparation for the testing provided by the Law on medicinal products, and will subsequently enter under the pharmaceutical authorization procedures.

CONCLUSIONS

Medical devices are indispensable for therapy, pharmacological, or non-pharmacological. Their evolution has led to an extraordinary diversification of the field and the emergence of industry related to the pharmaceutical industry, with specific laws and regulations. Medical devices play a very important role in modern medicine.

VARIA

Medical intervention in the biological attack with Bacillus anthracis

Viorel Ordeanu[1], Lucia E. Ionescu[1], Diana M. Popescu[1], Marius Necșulescu[1], Simona N. Bicheru[1], Gabriela V. Dumitrescu[1], Manuel Dogaru[2], Adrian A. Andrieş[3]

Abstract: *The biological agent most likely to be used as a biological weapon is Bacillus anthracis, which causes the anthrax infectious disease. During the Cold War, it was present in large quantities in the military arsenals of some states, and at the beginning of the 21st century was used in a series of small bioterrorist attacks. In case of occurrence of events using Bacillus anthracis, urgent and adequate qualitative and quantitative response measures are needed to manage the consequences of the attack and to reduce the effects on public health. These include complex and well-coordinated activities to ensure medical intervention for the prophylaxis, treatment and recovery of patients. General prophylaxis is achieved by vaccination, individual and collective CBRN protection, decontamination, partial and total sanitary treatment, microbiological analysis for the detection, identification and confirmation of the biological agent. Therapy for disease induced by weaponized B. anthracis differs from classic antrax disease regarding antibiotics, doses and time, resulting a large antibiotic consumption per case. Complete recovery of the patients is achieved not only in terms of restoring normal biological parameters, but also in terms of the organism's "sterilisation" regarding the causal biological agent.*

Keywords: *biological agent, antibiotherapy, anthrax, Bacillus anthracis, pharmacoeconomics, medical intervention*

INTRODUCTION

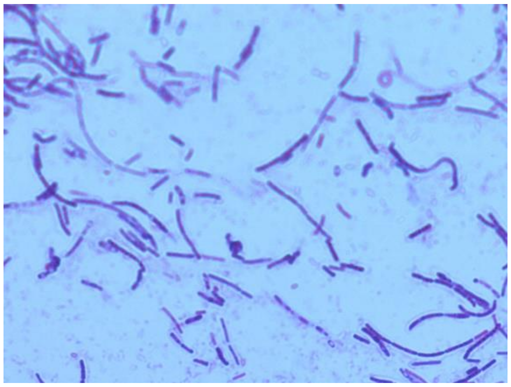
The biological attack, as an act of biological warfare or bioterrorism, occurs by attack with biological weapons, the biological agent being living (bacteria, viruses, etc.) or nevi (toxin, intermediates, etc.).

The most used biological agent, also confirmed by the existence of military arsenals or bioterrorist attacks in the 20th and early 21st centuries, is Bacillus anthracis, (sporogenous gram-positive bacillus) that causes anthrax infectious disease (Figure 1).

Anthrax spores can be disseminated by various means to produce a military attack with biological warfare agents (BWA), a limited bioterrorist attack, or a bio-crime against established targets (as they were in the US and EU in 2001 and 2002).

In order to reduce the effects on public health, urgent and adequate qualitative and quantitative response measures are needed to manage the consequences of the attack.

Figure 1: Bacillus anthracis 1119 R Stamatin – culture examined under a microscope x1500, (original)



These include medical intervention for the prophylaxis, treatment and recovery of patients [1, 2].

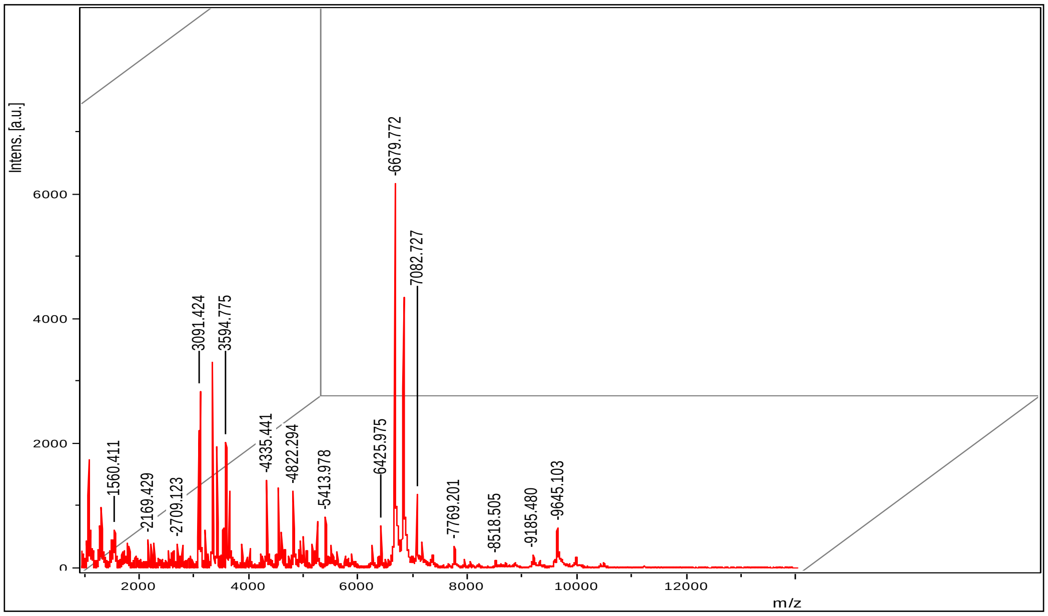
The general prophylaxis is achieved through health education, hygiene, vaccination, individual and collective CBRN protection, decontamination, partial and total health treatment, surveillance of suspects and contacts and, as the case may be, evacuation or isolation. It means that the medical service must collaborate with the veterinary service, the specialized military units, law enforcement agencies, local authorities and media representatives to disseminate accurate information, in order to reduce the epidemic and panic in the targeted community.

In practice, after a biological attack, the decontamination of the environment on large areas does not become an issue in terms of the excessive costs in using important forces and means, but only in terms of the personnel, the objects of strict necessity and of the access routes. The experience of the British army, on the island of Gruinard, is illustrative in this regard [3].

Although some authors consider (including in military textbooks) anthrax to be a non-contagious infectious disease, the risk of secondary contamination by manure, coughing and objects contaminated with bacteria in vegetative or sporadic form should not be overlooked. As a result, general precautions for anti-infective prophylaxis should be applied.

The diagnosis involves, as the case may be, an environmental stage with microbiological analysis for the detection, identification and confirmation of the biological agent in the air (if aerosolized), water, food, soil or different objects. This stage involves not only sanitary units (eg public health) but also military defense units against chemical, biological, radiological and nuclear weapons of mass destruction (WMD-CBRN), emergencies, secret services, etc. If contamination and disease are suspected, the task is of the human and/or veterinary medical service, which collects biological samples, cultivates, isolates and identifies with classical and/or modern means as well as confirmation by Polymerase chain reaction (PCR), Enzyme-Linked Immunosorbent Assay (ELISA) and Mass Spectrometry (Figure 2). Immediately after shall be established the pattern of susceptibility/resistance of the vegetative bacteria to antibiotics, for the orientation of the antibiotherapy. Some anthrax strains may be less pathogenic, anthrax-like or vaccine strains, which would lead to false alarms and the loss of credibility of the CBRN health and surveillance/defense service [4].

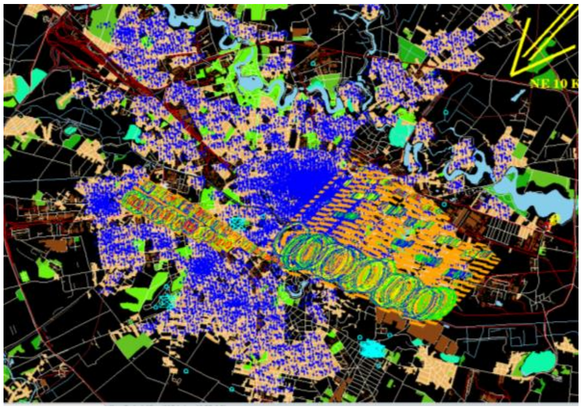
Figure 2: Bacillus anthracis - mass spectrometry diagram (original)



CLINICAL

Anthrax, also called charcoal, pustule, black sore, etc. is an acute infectious disease that naturally affects herbivores (horses, cattle, sheep, etc.) as zoonoses and epizootics, but can also be transmitted to humans, such as zooantroponosis and epidemic. Because the etiological agent B. anthracis is a telluric bacterium, a gram-positive bacillus that spores, therefore highly resistant to the environment, B. anthracis spores are considered the most likely biological agent for biological weapons and for bioterrorism, being confirmed by recent attacks. The spore itself is not pathogenic, because it does not have a metabolism and does not multiply, but it finds favorable living conditions (humidity, nutrients, heat, etc.) in the body that it contaminates and passes into vegetative form, which is pathogenic and causes the infection. For the biological attack on humans, domestic and wild animals or for the environment's contamination, it is estimated the use of strains of B. anthracis that are highly pathogenic, virulent, toxigenic, resistant to the environment and to the treatment with antibiotics (multiple antibioresistance), obtained either by selection either by genetic manipulation (Figure 3). As a result, biosafety measures must be respected, and treatment is intensive and prolonged [5, 9, 11-17].

Figure 3: Simulation of the dispersion of the biological agent Bacillus anthracis, 40 minutes report after aerosolization (original)



Depending on the pathway into the body and the location of the infection, the cutaneous anthrax (which has average severity) and the visceral anthrax are differentiated, with four clinical forms: gastrointestinal, pulmonary, meningeal and septicemic, which have a very serious prognosis.

Cutaneous anthrax the most common form of natural infection, most often occurs in animal breeders, is manifested by one or more characteristic "black sore", with a "charcoal" appearance (red-hot coal) with a red area and edematized around, painful, with medium-serious infectious and toxemic manifestations, but with reduced interhuman contagiousness. Classical antibiotherapy is applied (according to the infectious diseases manuals), symptomatic medication (anti-inflammatory, pain relievers, antipyretics), local antiseptics, dressing, possibly minor surgery.

Gastrointestinal anthrax (intestinal) caused by the ingestion of bacteria or spores with contaminated food or water that infects the gastrointestinal tract, with infectious and toxemic manifestations of high severity, with reduced human contagiousness, but with risk of environmental contamination. Classical antibiotherapy (according to infectious diseases manuals), symptomatic medication (anti-inflammatory, pain relievers, antipyretics), intestinal antiseptics, antidiarrheal and antiemetics are applied with caution. The waste will be collected and decontaminated energetically with conventional sporicidal disinfectants (chloride of lime, chloramine or formaldehyde).

Pulmonary anthrax (inhalation), caused by the inhalation of spores, in professional context or in aerosolization attacks for the deliberate release of spores. It is the most effective form of the biological attack, with infectious and toxemic manifestations of extreme severity: it is considered that morbidity is 99%, mortality over 90% in the untreated patients and about 50% in the treated patients. It is considered that it is not transmitted interhumanly, but we must also consider secondary aerosolization (from the patient) that can spread bacteria and spores through coughs, sneezes, saliva, etc. therefore precautions for air transmission must also be applied.

Other clinical forms of anthrax, more serious but rare, are actually complications of untreated disease, insufficiently treated or in immunocompromised organisms: meningeal anthrax and septicemic anthrax, in which mortality can reach 99%.

The incubation period for pulomonary anthrax varies between 1 and 60 days, depending on the host and the biological agent, and the patients often present: fever, discomfort, salivation, fatigue, low productive cough, nausea, vomiting and asfixia.

TREATMENT

The therapy for the disease resulting in a biological attack differs greatly from the classic recommendations, such as antibiotics (AB), doses and duration, achieving a very high consumption for each treated case. Our intention is to explain and complete the therapeutic procedures in the cases of anthrax resistant to treatment, as it can be the case in regards to BWA, bioterorist and biocrime attacks, with multi-resistant bacteria, in the patients with complications or immunosuppressed (by irradiation, intoxication or infections) etc. The old treatments were replaced or supplemented with antibiotherapy (ABT), which was a real breakthrough for the infectious disease clinic. But in the case of BWA, although this therapy is not wrong, it may not be effective: the bacterium is multi-resistant (AMR antimicrobial resistance), the clinical form is more serious, there should be a mass application treatment, so the therapeutic protocol differs. The causative agent of anthrax can persist in the body as a harmless spore and may become vegetative, thus pathogenic, later or even after the completion of the classic treatment. For this reason, after the attack with anthrax spores, post-exposure prophylaxis to contaminants and the anti-infective treatment in patients shall be continued without interruption for 60 days, according to the recommendations of the European Medicines Agency [6, 7, 8]. There is a risk of relapse and fallback, so treatment must be complex and individualized, but sometimes under mass therapy conditions. These conflicting requirements require continuous medical supervision and adequate health logistics [9].

There are no studies on humans for post-exposure prophylaxis with antibiotics, but experiments on guinea pigs and monkeys show that antibiotics from the cyclin and fluorinated quinolone groups, respectively Doxycycline and Ciprofloxacin, are the most effective in the prophylactic and curative treatment of anthrax [10]. However, any anti-infective treatment is important, because in the event of an epidemic, reserves of a certain antibiotic will be quickly depleted.

In the case of natural pulmonary anthrax (with "wild" bacillus) can be applied a complex treatment with classical antibiotherapy (according to the infectious diseases manuals), an adjunctive therapy (general or specific immunotherapy), complementary, symptomatic medication (anti-inflammatory, pain relievers, antipyretics), antiseptics, supporting vital functions (oxygen therapy, prosthetic respiration, etc.) and hospitalization in the AIC ward for infectious diseases.

In the case of the attack with aerosolized BWA, will be applied the principles of modern antibiotherapy, with antibiotic of choice or alternatives, for 60 days according to the recommendations of the EMA 2014 and the complex treatment depending on the specific situation. It turns out that in the case of an epidemic caused by a biological attack, the large number of patients who require the same special medical care and the same medicines creates a great problem of medical logistics.

Medical countermeasures may not be effective due to insufficient forces and means, which requires interinstitutional cooperation at local, national, European or international level. It should be noted that where the therapeutic recommendations state that "there is no recommended treatment" this does not mean that there is no treatment, but only that there is no specific treatment yet. So the doctor will apply any available treatment, which according to the medical logic and his experience, will heal his patient or will improve his condition, but in compliance with the classic principle "Primum non nocere" (Hippocrates). Regardless of the situation, no patient should be left without treatment.

Ciprofloxacin is recommended in the first line of treatment in two daily doses for 60 days [8], with all the pharmacological disadvantages it presents but the WHO has recommended caution with high and/or prolonged doses of ciprofloxacin treatment due to side effects such as tendon damage [18].

Other quinolones, such as Ofloxacin and Levofloxacin, offer options for alternative treatment, but dosage recommendations exist only for adults. Doxycycline and penicillins may be alternative therapies only if confirmed by susceptibility tests; Penicillin is not a safe bactericide on B. anthracis, but oral Amoxicillin is an alternative or continuation option if tolerated by the patient and if in vitro susceptibility is confirmed. B. anthracis can produce betalactamases, enzymes that hydrolyze penicillins [19].

Broad-spectrum antibiotics in prolonged treatment cause intestinal dysmicrobism and the microbiota should be protected with probiotics and the administration of useful bacteria if necessary.

The same antibacterial chemotherapics are recommended for the post-exposure prophylaxis, but Amoxicillin will be the drug of choice for pregnant women and young children, but only if the susceptibility tests are positive for penicillins.

Due to the high mortality in pulmonary anthrax, it is recommended to combine two or more antibiotics considered to be effective, the "therapeutic umbrella", but we do not have clinical trials for the multimedication therapy. Other active in vitro antibiotics that could be used in combination with Ciprofloxacin and Doxycycline are: protein synthesis inhibitors (Rifampicin, Chloramphenicol, Clindamycin, Clarithromycin, Erythromycin, Gentamicin, Streptomycin, etc.) and Vancomycin, but there is insufficient data to confirm their therapeutic efficacy in pulmonary anthrax [19]. Penicillins will not be used in combination with Ciprofloxacin. B. anthracis has a natural resistance to Sulfamethoxazole, Trimethoprim, Cefuroxime, Cefotaxime, Aztreonam, Ceftazidime etc., so these antibiotics cannot be used in the prophylactic or curative treatment of anthrax [10].

The injectable anti-infective treatment, although more effective, cannot be applied practically in the case of mass disease caused by a biological attack. Oral treatment is recommended if the patient can swallow and bioavailability is appropriate. As an example, Ciprofloxacin and Doxycycline are recommended for oral use [8].

Contraindications are those provided in the package leaflet, and as recommended by Prof. Ludovic Păun: "When prescribing an antibiotic, at least read the package leaflet!"

In pregnant and lactating women, shall be avoided the adminstration of risk products, breastfeeding will be discontinued and the treatment schedule shall be adapted accordingly. When applying any treatment, the axiom "There are no diseases, but patients" (Hippocrates) will be taken into account, and the complexity of the possible situations reminds us that medicine is equally science and art.

The present synthesis proposes therapeutic schemes for patients confirmed or suspected of pulmonary, gastrointestinal or cutaneous anthrax, and for the post-exposure prophylaxis in the case of confirmed or suspected exposure to B. anthracis, according to the studied bibliography and to the personal experience of scientific research of in vitro and in vivo anti-infective medical protection [19] and are presented by: International Common Denominator (ICD), role in therapy and prophylaxis, contraindications, dosage in treatment of suspected or clinically confirmed cases, post-exposure prophylaxis in confirmed or suspected cases of exposure to B. anthracis and duration of curative or prophylactic treatment. Depending on the clinical manifestations and situation, other anti-infective treatments, therapeutic serum (anti-carbonation serum, Cantacuzino I.), for supporting vital functions, immunomodulators, adjuvants, hygienic-dietary, psychotherapy, etc. will be applied.

In cutaneous anthrax with mild or medium forms, in which there are cases of spontaneous healing, the treatment will be done with the same dosage, but only for 7-10 days, and if there is a risk of inhalation of spores, the prophylaxis will last 60 days. In severe cases of cutaneous anthrax, with signs of systemic impairment, locally pronounced edema, with injuries to the head or the neck, a combined treatment will be applied [8].

The contraindications are those provided in the package leaflet, and in pregnant women and in lactation, the risk products will be avoided, breastfeeding will be discontinued and the treatment schedule adapted.

The dosage for children is calculated in mg/kg body weight, corresponding to a pharmacological reality, but without exceeding the adult dosage. From this it can be deduced that in adults with body weights significantly different from the average weight of 70 kg, therapeutic doses should be recalculated and we propose, for example, that individuals over 140 kg (without being obese) should be given double doses, if possible.

Antibiotherapy schemes according to EMA 2014

In the case of the BWA anthrax attack, the classical ABT is unlikely to be effective, due to changes in the "militarization" of the biological agent. As a result, AB will be used according to the EMA 2014 recommendations for biological agents, but also the antibiogram (ABG) will be used to confirm the spectrum of the isolated strain susceptibily/resistance from the patient.

Quinolones are the most important antibacterial chemotherapics in the treatment of anthrax.

Ciprofloxacin is the treatment of choice and is an alternative to continuing oral treatment, and is the first choice in prophylaxis until confirmation of the susceptibility of other antibiotics.

The dosage for the curative treatment of pulmonalry and gastrointestinal anthrax in adults (over 15 years) is initially 400 mg i.v. twice daily, continued with 500 mg p.o. twice a day for 60 days, totaling 60 g of the active substance. In children (under 15 years) is initially 15 mg/kg body weight i.v. twice a day, continued with 15 mg/kg body weight p.o. twice a day, (the daily dose should not exceed the adult dose) for 60 days.

Posology for the prophylactic post-exposure treatment in adults is 500 mg p.o. two times a day, for 60 days, totaling 60 g active substance, and in children 15 mg/kg body weight daily twice a day, (the daily dosage shall not exceed the adult dose), for 60 days.

It is known that antibiotics are among the most widely used drugs, and their costs are not very high. But in countries where compulsory health insurance operates, costs per dose can be increased by an order of magnitude. As a result, the costs per treatment must be compared, because for a large number of patients the total costs can be very high, so the principles of pharmacoeconomics will apply.

Ofloxacin is an alternative to Ciprofloxacin. The dosage for the curative treatment of pulmonary and gastrointestinal anthrax in adults (over 15 years) is initially 400 mg i.v. twice a day, continued with 400 mg p.o. twice a day for 60 days, totaling 48 g of active substance. The dosage for prophylactic post-exposure treatment in adults is 400 mg p.o. twice a day for 60 days, totaling 48 g of active substance.

Levofloxacin is an alternative to Ciprofloxacin. The dosage for the curative treatment of pulmonary and gastrointestinal anthrax in adults (over 15 years) is initially 500 mg i.v. once a day, continued with 500 mg p.o. once a day for 60 days, totaling 30 g of active substance. The dosage for prophylactic post-exposure treatment in adults is 500 mg p.o. once a day for 60 days, totaling 30 g of active substance.

Modern cyclins represent the optimal alternative antibacterial treatment.

Doxycycline is the alternative choice treatment and continuation of oral treatment, and is the first choice in prophylaxis if the sensitivity of the B. anthracis strain is confirmed.

The dosage for the curative treatment of pulmonalry and gastrointestinal anthrax in adults (over 15 years) and in older children 8-15 years, over 45 kg) is initially 100 mg i.v. twice a day, continued with 100 mg p.o. twice a day for 60 days, totaling 12 g of the active substance. In older children (8-15 years, under 45 kg) and in younger children (under 8 years) is initially 2.2 mg/kg body weight i.v. twice a day, (the daily dose should not exceed the adult dose) continued with the same oral dosage for 60 days, totaling 12 g of active substance.

The dosage for prophylactic post-exposure treatment in adults (over 15 years and in older children 8-15 years, over 45 kg) is initially 100 mg i.v. twice a day, for 60 days, totaling 12 g of the active substance and in children 15 mg/kg body weight twice a day (the daily dose should not exceed the adult dose). In older children (8-15 years, under 45 kg) and in younger children (under 8 years) is initially 2.2 mg/kg body weight i.v. twice a day, continued with the same oral dosage for 60 days, totaling 12 g of active substance.

Some beta-lactams may be used as an alternative antibacterial treatment, depending on the susceptibility of the B. anthracis strain.

Penicillin G is an alternative to first-line treatment if bacterial susceptibility is confirmed and penicillin allergy is excluded.

The posology for the curative treatment of pulmonary and gastrointestinal anthrax in adults (over 15 years and in older children 12-15 years) is 3 g (approx. 3 MUI) i.v. (preferably brannule infusion) 6 times a day (every 4 hours), for 60 days, totaling 1,080 g in 360 sessions (!?). In children (under 12 years) 30 mg/kg body weight, 5 times a day, for 60 days. It is not administered for post-exposure prophylaxis.

Amoxicillin is an alternative to first-line treatment and oral prophylaxis if bacterial susceptibility is confirmed.

Posology for the curative treatment of pulmonary and gastrointestinal anthrax in adults (over 15 years) 1 g i.v. 3 times a day, followed by 500 mg p.o. 3 times a day for 60 days, totaling 91.5 g of the active substance. In children (under 15 years), 80 mg/kg body weight per day, i.v. divided into 3 doses, followed by 80 mg/kg body weigh per day, p.o. divided into 3 doses (without exceeding the adult dose) for 60 days.

Posology for the prophylactic post-exposure treatment in adults (over 15 years) is 500 mg p.o. three times a day, for 60 days, totaling 90 g active substance, and in children is given 80 mg/kg body weight daily, p.o. divided into 3 doses, without exceeding the adult dose, for 60 days.

The recovery of the patients shall be considered not only in terms of restoring health but also in terms of the "sterilization" of the causal biological agent, so it is long lasting even in the case of an apparent cure.

Pharmacoeconomics

In case of a mass contamination or illness, very large quantities of specific antibacterial chemotherapics are needed, and the supply and replenishment of the sanitary units involved will impose significant financial costs, sometimes prohibitive. It turns out that, in addition to the pharmacological requirements, it is compulsory to take into account the criteria of pharmacoeconomics, for which we present below some examples, which can be found and/or updated on dedicated sites, on the Internet [20, 32, 33, 34].

“The wholesale cost of Ciprophloxacine in the developing world is between US$0.03 and US$0.13 a dose” [14]. In the United States it is sold for about US$0.40 per dose.

“Ofloxacin was patented in 1980 and approved for medical use in 1985 [21]. It is on the World Health Organization's List of Essential Medicines, the most effective and safe medicines needed in a health system”. Ofloxacin is available as a generic medication [22]. The wholesale cost in the developing world is about US$3.27 per month [23]. In the United States a course of treatment costs about $50–100. The wholesale cost in the developing world is about US$3.27 per month [24]. In the United States a course of treatment costs about $50–100.

“Levofloxacin was approved for medical use in the United States in 1996. It is on the World Health Organization's List of Essential Medicines, the most effective and safe medicines needed in a health system [25]. It is available as a generic medication” [24]. “The wholesale cost in the developing world is about US$0.44–0.95 per week of treatment. In the United States a week of treatment costs about $50–100. The wholesale cost in the developing world is about US$0.44–0.95 per week of treatment” [26]. In the United States a week of treatment costs about $50–100.

Doxycycline is available as a generic medicine and is generally inexpensive [27, 28]. “The wholesale cost in the developing world is between US$0.01 and $0.04 per pill. In the United States 10 days of treatment is about US$14; however, some in 2014 were selling it for more than $3.00–10.00 per pill. The wholesale cost in the developing world is between US$0.01 and $0.04 per pill” [29]. In the United

States 10 days of treatment is about US$14; however, some in 2014 were selling it for more than $3.00–10.00 per pill.

Benzylpenicillin was discovered in 1929 by Alexander Fleming and came into commercial use in 1942 [30]. It is on the World Health Organization's List of Essential Medicines, the most effective and safe medicines needed in a health system [31]. The wholesale cost in the developing world is about US$0.24–2.72 per day [32]. In the United States a course of treatment costs $100–200.

Amoxicillin is available as a generic medication [33]. It has a wholesale cost in the developing world of between US$0.02 and 0.05 per pill [34]. In the United States, ten days of treatment costs about US$16 ($0.40 per pill).

OBSERVATION

The medical intervention for the prophylaxis, treatment and recovery of the patients includes an antibiotherapy that differs much from the classic recommendations, like antibiotics, doses and duration, realizing very high consumptions for each treated case and indeed huge for the winding up of the consequences of the biological attack. The biological agent must be detected, identified and confirmed as soon as possible, in the environment, in humans and animals and in patients for etiological diagnosis and antibiogram. Depending on the epidemiological triage, it is necessary to determine exactly who needs curative treatment, who is taking prophylactic treatment and who should be kept under medical supervision.

The anti-infective treatment should be personalized and supplemented as appropriate with other medicines: specific biological products (anti-carbon serum for the seriously ill, vaccine for those at risk of exposure), non-steroidal anti-inflammatory and pain relievers (aspirin, paracetamol etc.), antipyretics, antitussive, oxygen with or no assisted breathing, antiseptics, disinfectants, etc. Currently, there is a big problem at national level: the main producer in Romania, of biological products for treatment and diagnosis, INCDMM Cantacuzino, no longer has the marketing authorization for prophylactic and therapeutic vaccines, therapeutic and immunomodulatory sera, being undergoing re-technologization.

The seriously ill should be hospitalized, preferably in hospitals with existing infectious-disease wards or improvised in civilian sanitary units through civil-military cooperation (CIMIC) or by transforming some field hospitals (specialized in the management of polytrauma). The other patients, suspects and contacts, if large in number, will be treated and supervised by existing CIMIC forces and means, and if these shall not suffice, with international support from EU, NATO, WHO, etc.

The therapeutic schemes presented in this paper have been extracted from the specialized literature, being suggested as treatment alternatives in the case of pulmonary anthrax with resistant germs, or for the situations in which the resources have been exhausted and other therapeutic strategies should be used to avoid high risk situations for the public health, in the case of biological attack with B. anthracis. Pharmacoeconomic comparisons are presented, both for the guidance of clinicians and health decision-makers [35-49].

It should be noted that in the case of other bacterial biological agents, including BWA, the therapeutic schemes (post-exposure prophylaxis and curative treatment) range between 10-20 days, with usual antibiotics, ensuring medical countermeasures being much easier to achieve from a logistical standpoint.

CONCLUSIONS

The biological attack with B. anthracis is possible, as much as biological warfare, bioterrorist attack or biological accident. The management of the consequences also includes medical intervention, which is essential in combating and eliminating the effects of the attack with B. anthracis. The biological agent must be detected, identified and confirmed as soon as possible, in the environment, in humans and animals and in patients for etiological diagnosis and antibiogram.

The medical intervention for the prophylaxis, treatment and recovery of the patients includes an antibiotherapy that differs much from the classic recommendations, like antibiotics, doses and duration, achieving very high consumption per treated case and indeed huge for the liquidation of the consequences of the biological attack. Specific therapeutic schemes should be known by physicians and pharmacists for practical application, but also by the decision makers for setting up health stocks and could be integrated in the management of the consequences of the biological attack.

We believe that by applying the specific complex measures presented, the morbidity and mortality following the biological attack with B. anthracis can be reduced to an acceptable level, common for infectious diseases.

Special thanks

This paper was written as a dissemination of some Research Projects PSCD/MApN, financed by the Ministry of National Defence in Romania.

Metformin – old treatment for diabetes, new treatment for psoriasis

Bogdan Serban[1,2], Camelia C. Diaconu[1,3], Ana Maria A. Stanescu[1], Daniel O. Costache[4], Raluca S. Costache[1,4], Catalin Cirstoiu[1,2]

Abstract: *Metformin was a revelation in the treatment of patients with type 2 diabetes, being widely used, with remarkable outcomes. Lately, research has greatly expanded the indications of metformin treatment, which can be used not only in diabetes but also in many other conditions. Although still debatable, several studies have shown the beneficial effects of metformin treatment in patients with psoriasis. This article is a review of the latest data of scientific literature about the effects of metformin administration in patients with diabetes and psoriasis, but also in nondiabetic patients with psoriasis.*

Keywords: *metformin, diabetes, psoriasis*

INTRODUCTION

Psoriasis is a chronic inflammatory disorder characterized by hyperproliferation and inflammation of keratinocytes. Psoriasis is a complex disorder, both from the standpoint of the disease and from the many associated comorbidities. Obesity, diabetes, metabolic syndrome, arthritis and cardiovascular disease are the most common comorbidities in patients with psoriasis [1, 2, 25]. Pathophysiologically, patients with psoriasis present changes of the tumor necrosis factor alpha and interleukins [6, 8, 12, 17, 19 and 23], highlighting the pathophysiological link with the metabolic syndrome [3]. There is a two-way link between psoriasis and diabetes, patients with psoriasis are at risk of developing diabetes, while patients with diabetes are at risk of developing psoriasis [4, 5].

Numerous therapies are available for the treatment of psoriasis, from topical to biological. Many of the current therapies for psoriasis are expensive and/or may cause toxicity; new and more accessible therapies with reduced adverse effects are needed.

Metformin, a herbal remedy, was first synthesized in 1922, and subsequently Jean Sterne highlighted the properties of the metformin as Glucophage compound (glucose eater) (6). Metformin is largely used in the treatment of diabetes, being accessible, easy to administer, with few side effects and with potential to decrease the body weight in obese patients. Since 2009, metformin has been recommended by the American Diabetes Association (ADA) and the European Association for the Study of Diabetes (EASD) in patients with type 2 diabetes as first-line oral therapy [7]. Many studies focused on the potential benefits of metformin administration in patients with diabetes and other conditions.

Although generally well tolerated, metformin has a number of contraindications to administration (Figure 1).

METFORMIN IN THE TREATMENT OF DIABETES

Metformin is widely used for the treatment of type 2 diabetes. It is a first-line treatment as monotherapy or can be used as a combination therapy when monotherapy is no longer effective; insulin (regardless of the number of insulin injections/day) can be combined with a sulphonylurea, incretin or flozin [8]. In addition to the potential of lowering high blood glucose, metformin has a favorable effect on body weight, a very important aspect in diabetic patients.

Metformin does not cause hypoglycemia, because it does not stimulate the insulin secretion by the beta cells of the pancreas, the effect of lowering the serum glucose is due to inhibition of hepatic glucose production and sensitization of peripheral tissue to the effect of insulin.

Kirpichnikov et al emphasized the ability of metformin to reduce hemoglobin A1c by 1.3% - 2%, and may have a higher degree of reduction in patients with higher blood glucose levels during pre-treatment [9]. Although lifestyle changes seem to be more effective in the prevention of type 2 diabetes in people at risk, metformin can reduce the progression of diabetes and can be administered from the age of 10 years [10].

Following the administration of metformin in diabetics, in addition to the glucose-lowering effects, an improvement not only in the cardiovascular morbidity and mortality has been noticed, but also in the general health [11]. From the cardiovascular point of view, in patients at risk, the benefit of metformin administration is observed by the reduction of the body stress consequently to lower glucose levels, reducing the risk of myocardial infarction or arrhythmias.

In addition to the administration of metformin in type 2 diabetes, recent studies focused on its administration in type 1 diabetes. Nadeau et al, following the administration of metformin in patients with type 1 diabetes, observed a decrease in insulin dose, an improvement in body mass index and a decrease in waist circumference, especially in women [12]. Libman et al, in their study, have found that HbA1c was not significantly decreased following metformin administration, although the decrease in insulin dose was noted, and the patients complained of gastrointestinal distress [13]. Other observations following metformin administration in type 1 diabetes were improved outcomes of heart failure (regardless of decreased hemoglobin A1c) and decreased androgen levels in women with type 1 diabetes and hyperandrogenism [14, 15].

The benefits of using metformin in pre-diabetes were highlighted by the study of Capitanio et al, who have noticed a reduced risk of type 2 diabetes (by 31%) and a reduction of the body weight by average 2 kg in those who used metformin [16]. People with prediabetes should reduce their body weight and increase their daily physical activity; in addition, metformin can be considered for the prevention of type 2 diabetes in people at risk.

METFORMIN IN THE TREATMENT OF PSORIASIS

Starting from the pathophysiological mechanisms of psoriasis, with hyperproliferation and abnormal differentiation of epidermal keratinocytes, the main method of treatment of psoriasis focuses on inhibiting the excessive proliferation of keratinocytes [17}. HaCaT are cell lines derived from keratinocytes in normal adult skin, and excessive proliferation of these keratinocytes results in psoriatic lesions, with HaCaT cells being used as an in vitro model for the study of anti-psoriasis agents [18].

He et al investigated the effects of metformin on the proliferation of human immortalized keratinocytes. Metformin treatment regulated the level of p-AMPK and p-ERK1/2 in HaCaT cells and significantly inhibited the proliferation of HaCaT cells in vitro, by a mechanism associated with activation of the protein signaling pathway, mitogen-activated kinase [19].

Xuan et al have found differences in the quality of life of patients with psoriasis treated with metformin plus methotrexate, compared with patients treated with methotrexate alone. Combined metformin + methotrexate therapy contributes to a significant improvement in the quality of life of patients with psoriasis [20].

Because many psoriasis patients have also metabolic syndrome, Singh and Bhansali studied the effects of metformin (1000 mg/day) on the metabolic syndrome in psoriatic patients. These authors showed a marked improvement of the metabolic syndrome, following metformin administration, at 52.4%, compared with placebo (metformin versus placebo – OR (95% CI), 5.2 (1.3–20.7), P value 0.019) [21}. The proven efficacy of metformin on the metabolic syndrome is a potential axis for improving psoriasis. Because of metformin administration, 14.3% of patients compared with placebo (10%) had no changes or increases in IL-6 and TNF-α, followed by recurrence of psoriasis within the next 6 months [21].

Brauchli et al estimated a low risk of developing psoriasis (as a new diagnosis) using metformin compared to controls [OR = 0.77 (95% CI - 0.62-0.096)] [22].

Regarding the safety of metformin administration in patients with psoriasis and diabetes, it did not cause increased mortality, did not increase the severity of psoriasis or the rate of hospitalization for any other reason, metformin being safe to administer to patients with psoriasis [23].

Wu et al looked at the risk of developing psoriasis in patients with diabetes depending on the antidiabetic medication; they observed an increased risk of developing psoriasis in people with severe diabetes under insulin treatment, while the risk of developing psoriasis was not associated with metformin [5].

Starting from the cases of lichenoid rash and erythema multiforme that appeared following the administration of oral antihyperglycaemic drugs, we have found in the scientific literature only a case published in 2003 (possibly the first of this type reported), who suggests the occurrence of psoriatic rash following the administration of metformin, which eruption recovered after stopping the drug and reappeared with the reintroduction of the drug [24].

In addition to the proven beneficial effects of metformin on psoriasis, it seems that it has other applications in dermatology. Among the dermatological disorders studied from the point of view of metformin administration are acanthosis nigricans, acne, disorders of increased pigmentation, eruptive xanthomas, suppurative hidradenitis, hirsutism, skin cancer, squamous cell carcinoma, and melanoma.

CONCLUSION

The more extensive the metformin research areas, the more therapeutic applications appear. From the point of view of psoriasis, the use of metformin is safe and beneficial. Further studies are needed to determine the optimal dose of metformin recommended in patients with psoriasis, depending on the associated comorbidities.

Mg-1Ca alloy intramedullary nailing influence on bone callus formation and on vital organs functions, as an alternative to bioplastics

Razvan Adam[1], Iulian Antoniac[2], George M. Avram[3], Marius Niculescu[4]

Abstract: *Magnesium alloys represent a new research direction in the field of orthopedic resorbable metal materials, because it has several important properties that recommend it as an excellent resorbable biomaterial for implants. From in vitro studies, Magnesium has osteoconductive properties, promoting the formation of new bone by stimulating the adhesion of osteoblastic cells, this leading to the idea that it will induce formation of hard callous at fracture site. The present study followed the in vivo evaluation of the biodegradation of pins made of Mg-1Ca alloy introduced centromedulary in rabbit tibiae, with previously induced experimental fractures. The influence of the biodegradation process on the formation of the bone callus was evaluated through radiological images and histopathological examinations. At the same time, we evaluated the function of vital organs through histopathological examinations and blood tests. We chose intramedulary nailing (IMN) with pins, because in orthopaedic surgery this is the golden standard for fractures of tibia or femur. In the radiological images obtained, we notice callus formation at the level of the experimental fracture at 6 weeks after surgery. The histological sections made from the samples collected from the fracture zone adjacent to the Mg1Ca alloy implant, confirm the formation of the bony callus. The trichrome Masson sections show a normal bone development with newly formed bone tissue at the tissue - alloy interface. In the sections harvested from the vital organs, no pathological changes are observed. These observations suggest that the biodegradation process of the Mg-1Ca alloy do not interfere negatively with the biological process of bone formation, allowing the formation of the bone callus and do not confirm the suspicion of pathological changes induced by systemically released corrosion products and gas embolism in vital organs.*

Keywords: *magnesium, alloy, implant, pins, biodegradation*

INTRODUCTION

Magnesium alloys represent a new research direction in the field of orthopedic resorbable metal materials. Use ofbioabsorbable materials will eliminate the need for a second ablation intervention leading to reduction of patient stress, reduction of postoperative infection risk and medical cost reduction. Also, it will have the advantage of reduction of bone/implant contact stress effect (stress shielding effect) and load transfer, gradually during resorption, toward the newly formed bone in the same time with resorption, decreasing the risk of fracture after surgery, as in the case of metal one

Main requirements of bioabsorbable metal materials are biocompatibility and biological functionality, physiological material without rejection reaction, that will assist the bone repair. In the same time it will need to have physicochemical properties consistent with the physiology of the region, meaning, no toxicities when resorption occurs, bone adhesion and allowing bone cell proliferation (osteoconductive), resorption by biodegradation and bone remodeling. Other recent studies in biomaterials have yet to take into account the possibility of bioabsorbable metal as an option [1], while others rely on biocompatibility without bioresorbtion [2, 3].

Mg1Ca alloy

Mg-1Ca alloy consists in two natural elements of the human body, being able to dissolve in the body without inducing toxicities and foreign body reactions. Magnesium has osteoconductive properties, promoting the formation of new bone by stimulating the adhesion of osteoblastic cells, this leading to the idea that will induce formation of hard callous at fracture site.

Calcium is an important component of bone tissue and is an essential element in biochemical processes. It have a low density, 1.55 g/cm^3, which enables Mg-Ca alloys to achieve a density similar to bone, wich is 1.8 – 2.1 g/cm^3. Also, Magnesium has the potential to improve the incorporation of calcium into bone. Mg-Ca alloys are the most used and researched alloys, the solubility of Ca in Mg is 1.34 wt% [4].

The main drawbacks of Mg alloys are rapid biodegradation, increased rate of corrosion in the body, at a physiological pH of 7.4 to 7.6. Rapid corrosion will lead to loss of mechanical capabilities, the bending strength being able to decreasein a first stage of erosion from 652 MPa to 390 MPa [5].

Also, rapid corrosion will increase ph in the corrosion environment, thus producing a alkalizing effect of peri-implant tissues, with cytotoxic effect. According to ISO 10993-5:2009, a reduction of cell viability more than 30% it is considered a cytotoxic effect [6].

During corrosion process of Mg-Ca, hydrogen gas will be released. High hydrogen evolution rate corresponding to a high corrosion rate, will lead to gas bubbles formation into the surrounding tissues, leading to tissue necrosis, surgical incision dehiscence [7] and risk of gas embolisation in vital organs [8].

Mg-Ca alloys have a binary microstructure, consisting of a primary phase, α Mg, and an eutectic secondary phase, with lamellar structure, composed of Mg_2Ca [9]. Mg-Ca alloys corrosion process is the result of a galvanic circuitformation, due to the electrochemical potential difference between the primary phase α Mg and the secondary phase Mg_2Ca. Mg-Ca alloys undergo in SBF the corrosion process shown in figure 1:

a) galvanic corrosion of Mg and Mg_2Ca phase;

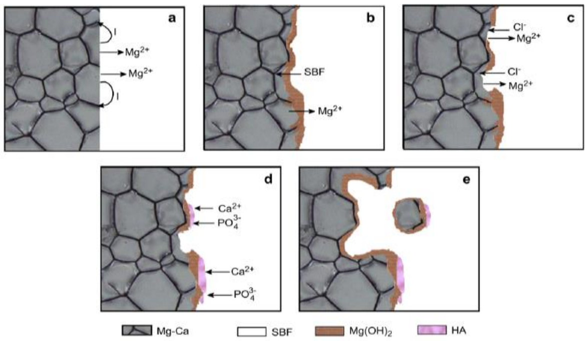
b) partially protective layer covering the surface of the Mg-Ca alloy;

c) absorption of chlorine ions for the conversion of $Mg(OH)_2$ to $MgCl_2$;

d) hydroxyapatite formation by consuming Ca^{2+} and $PO4^{3-}$ ions;

e) particulate residues decay emerging from the substrate volume.

Figure 1: Mg-Ca alloy corrosion in SBF (adapted after 8)



Based on this type of corrosion, literature studies concluded that controlling the amount of calcium in the alloy will influence corrosion rate and mechanical properties. Thus results obtained on alloys with low calcium concentrations, 1, 2 and 3% were better than those with high concentrations (5% - 20% Ca) both in terms of mechanical properties and corrosion rate [4, 10, 11], Mg-Ca 1% alloy being considered to be optimal for orthopedic implants [12].

Another method of improving the mechanical properties of Mg-1Ca alloys in the molded state is secondary mechanical processing. The tensile strength of the alloy has recorded, initially, a value of 71.38 ± 3.01 MPa. Through the process of hot rolling it reached a value of 166.7 ± 3.01 MPa, and by hot extrusion it was improved up to a value of 239.63 ± 7.21 MPa [12]. In the same time, this method improved hydrogen emissions meaning that corrosion rate is improved (high corrosion rate equals high hydrogen release). Diminished corrosion rate of the Mg-1Ca alloy, processed by hot extrusion has been expressed by a low hydrogen emission rate, from 35 ml/cm^2 to 10 ml/cm^2 [12].

During corrosion process, a hydroxyapatite layer is formed on the surface of the alloy, having a positive role on bone cell adhesion. Also, magnesium ions resulting from the degradation of the Mg-1Ca alloy, Zreiqat [11], could increase cell adhesion of HBDC (Human Body Derived Cells) in cell cultures. At the level of HBDC cells grown on the surface of the alloy, increased levels of α5b1 and b1 integrin receptors were discovered, which play a role in mediating cell adhesion to the surface of biomaterials. Thus, it is assumed that the increased viability expressed by Mg-1Ca alloys in cell cultures can be explained by facilitating the early response of osteoblasts, and it can be inferred that the release of Mg^{2+} ions from the alloy can stimulate bone cell adhesion and proliferation, being raised the hypothesis of the positive role of Mg-1Ca alloys in bone healing.

This research comes in suite with other areas of development in material science for orthopedic use in the local geographic area focusing on the interaction between the organic and the inorganic and also focusing on the impact of this research on the patients' lives [13, 14].

MATERIAL AND METHOD

Four specimens of domestic rabbit "Oryctologus Cuniculus", adult, minimum weight 3.5 kg, were used, divided in two groups. Group 1, included 3 specimens, with experimental fractures. Two rabbits with experimental fracture al anterior tibial tuberosity level and one with tibial diaphysis accidental fracture, during Mg-1Ca implant insertion. Fracture site was stabilized by the cylindrical implant followed by spica cast for three weeks. Group 2, control one, included one rabbit with a subtrochanteric fracture, occurred during a Mg-1Ca implant insertion (another experiment). In order not to lose the specimen, we extracted the magnesium alloy and continued with the hip osteosynthesis, plate and screws, austenitic steel.

We had used cylindrical implants of Mg-1Ca alloy, cast, with a density of 1.78 g/cm^3 and dimensions: L 40 mm, diameter 3.2 mm (Figure 2).

Figure 2: Mg-1Ca nail

We chose intramedulary nailing (IMN), pins, because in orthopaedic surgery this is the golden standard for fractures of tibia or femur. This hypothesis is supported by biomechanical and biological factors.

Because of its design and mode of insertion, in the center of the bone, respecting the anatomical and mechanical axis of the bone, IMN is a load sharing implant compared to plates that are load bearing implants. This will increase the load bearing capacity of the implant, in the same time decreasing the stress shielding effect, fractures around the implant being less. Considering these characteristics, load bearing will be allowed earlier compared to plates osteosynthesis.

Regarding the biological factors , IMN will lead to less soft tissue damages compared to plates osteosynthesis. Fracture healing is a periosteum depended process and IMN will preserve it and also it will preserve the hematoma formed around the fracture site, that is a source of mediators for the bone callus formation process. Also, IMN is less invasive and the infection rate is low.

Another reason why we chose the intramedullary nailing system method is that the main objective of the study is to investigate the interaction of Mg-1Ca biomaterial with bone tissue. As we have shown in preliminary studies, the corrosion rate of Mg 1Ca alloy in contact with bone tissue is different from that in contact with muscle tissue. Unlike IMN which provides contact of the alloy only with bone tissue, plate and screw osteosynthesis will lead to two areas of contact of the alloy, with bone tissue and muscle tissue. This can generate false negative or false positive data, which can alter the results of the study.

The study was carried out with approval of the Ethics Committee for Scientific Research, no 92/20.04.2016, code PO-35-F-03. Animal care and clinical evaluation were performed according to FELASA (Federation of European Laboratory Animal Science Associations) guidelines and recommendations [15].

Preop procedures: Lower limbs radiographs, in two incidents, anterior-posterior and laterally, Figures 3 and 4. The animals were dewormed using Ivermectin, at a dose of 0.1 ml/body kg, subcutaneously (SC). Preoperative antibiotic therapy , one dose of Enrofloxacin (Boytril 5%) at a dose of 10 mg/body kg, subcutaneous.

Figure 3: Preoperative Xray

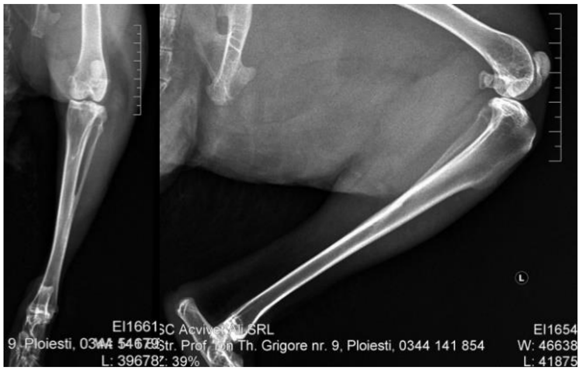


Figure 4: Preoperative Xray control group

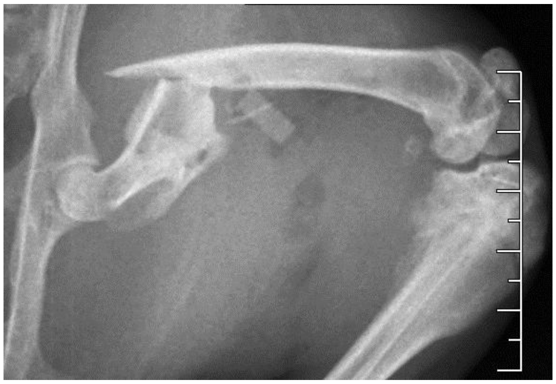


Blood tests: are needed to evaluate the possible impairment of the function of the vital organs, kidney, liver or ionogram by the corrosion of the alloy.For the blood samples we used as a source the auricular artery. All determinations of blood parameters were performed using the services of accredited laboratories. The determined parameters and their physiological values are represented in the following Tables (1 and 2).

Table 1: Ionogram

Element	Normal value
Magnesium	2.19 – 4.14 (mg/dL)
Calcium	12.4 – 15.6 (mg/dL)
Sideremia	111.7 – 329.6 (μg/dL)
Sodium (Na^+)	138 – 155 (mmol/L)
Potassium (K^+)	3.7 – 6.3 (mmol/L)

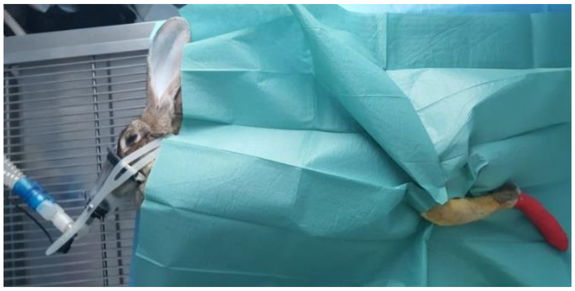
Table 2: Vital organ tests

Element	Normal value
Serum urea	12.6 - 50.3 (mg/dL)
Creatinine	0.38 - 1.88 (mg/dL)
Alanaminotransferase (ALT)	<61 (IU/L)
Aspartataminotransferase (AST)	<28 (IU/L)

Surgical procedures: The implants were chemically sterilized by ethylene oxide sterilization method, thus avoiding damage to the alloy.

The type of anesthesia chosen was, mask inhalation anesthesia, veterinary use (Figure 5). For induction Ketamine 20mg/body Kg, subcutaneous (s.c.) was used. The anesthetic agent used was: Sevoflurane.The anesthesia was maintained by sevoflurane delivered in oxygen (1.5–3.5% oxygenmixture; 1.5 L/min) Throughout the surgery we monitored cardiac activity and respiratory movements. Infusion of Ringer’s lactate solution(10 mL/kg/h) during the entire surgical procedure ensured cardiovascular function.

Figure 5: Anesthesia



The surgery consisted of centromedular implantation, proximal tibia, cylindrical implant Mg-1Ca alloy, nail type by approach over the anterior tibial tuberosity (Figures 6, 7), followed by an experimental fracture, with oscillating saw, in tibial diaphysis at a distance of 1 cm distal of anterior tibial tuberosity (Figure 8).

Figure 6: Mg alloy implant insertion

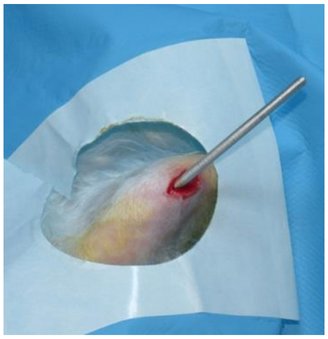


Figure 7: Mg alloy implant insertion

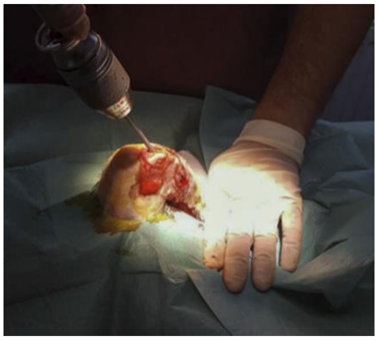

Figure 8: Experimental fracture

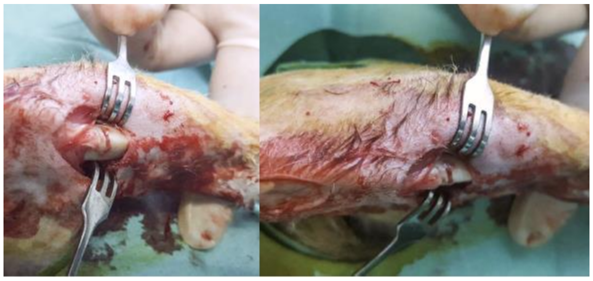

Postoperative procedures: Prophylactic antibiotic therapy, two days post-operatively. Enrofloxacin (Boytril 5%) at a dose of 5 mg/body Kg/12 hours, (s.c.) was used. Postoperative pain was controlled using Meloxicam at 0.2 mg/body Kg/24 hours (s.c.).

Two incidents radiographs, anterior-posterior and lateral, were used, with the same radiological device and the same technical data as in the case of pre-operative radiographs. Radiological follow up was for 6 weeks, and it is necessary to highlight the resorption of implants, and bone callus evolution.

At 6 weeks postoperatively, blood samples were collected.

Blood parameters and harvest conditions were similar to those performed preoperatively.

Euthanasia of rabbits was performed 6 weeks after implantation. In order to eliminate the suffering of the animals, we chose as an initial procedure their anesthesia, performed by s.c. Ketamine injection at a dose of 20 mg/body Kg. After this, euthanasia was performed by injecting 1 ml T61 (Etambutramide + Mebezonium Iodide + Tetracaine hydrochloric) intravenous (i.v.).

Post-euthanasia procedures: proximal tibialhalf, wasblock harvested, including bone callus formation area, and Mg-1Ca implant included insidethe bone piece, directly after sacrifice and fixated in 4% formaldehyde for postmortem histological analysis. We aimed to highlight the formation of bone callus in the fracture site, to highlight the cell viability, the morphology of the bone cells in the immediate vicinity of the Mg-1Ca alloy implant and those from the bone callus. The slides were analyzed using a Niko Eclipse E200 optical microscope, connected to a computer for the extraction and analysis of the obtained images. Bone tissue samples were decalcified in 10% EDTA solution. After decalcification, 4 µm thick sections were fixed in paraffin blocks, from which microtomes were cut. The sections were fixed on examination blades and colored. The staining method was Hematoxylin-Eosin, Van Gieson and Trichrome Masson. We also harvested tissue samples for histological examination from vital organs such as lungs, kidney and liver due to the suspicion of gas embolization in the vital organs and the influence of the resorption process of the Mg-1Ca alloy on the function of these organs, the same that I assessed through the laboratory tests. The slides were analyzed using the same type of microscope as before, and the staining method was Hematoxylin-Eosin.

RESULTS

The radiological follow-up after surgery in shown in Figure 9.

Figure 9: ATT fracture group, Mg-1Ca implant marked with no 1, fracture site marked with no 2.

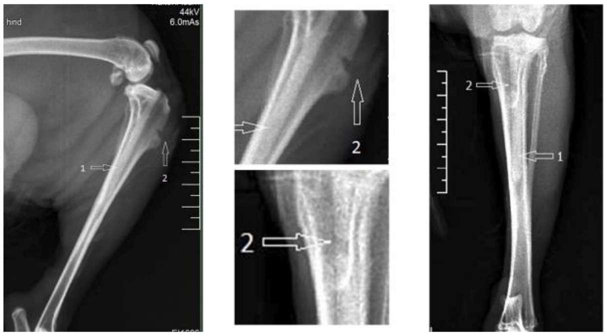

Figure 10 shows the accidental fracture of the tibial diaphysis that occurred during the introduction of Mg alloy implant. Figure 11 shows the control specimen, austenitic steel plate and screws osteosynthesis, marked with no 1.

Figure 10: Accidental fracture

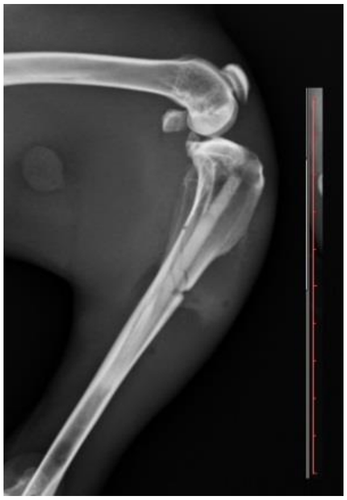

Figure 11: Control specimen

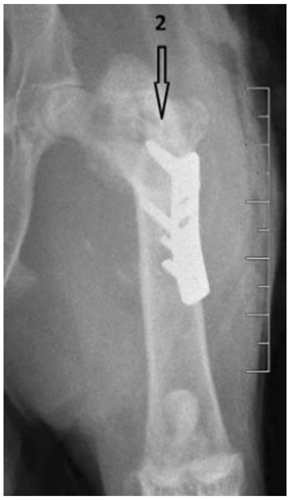

Six weeks after surgery

The situation of the experimental fracture at 6 weeks is presented in Figure 12. The fracture is healed, bone callus is noted with no 2. The implant from the Mg-1Ca alloy, Figure 1, is partially resorbed, especially in the metaphyseal area, but the shape is still preserved. The gas bubbles, no 3, are present in a small quantity, especially at the joint level. In the area adjacent to the implant, in contact with its surface, opaque areas, no 4, are observed, signs of mineralization. Figure 13 shows the accidental fracture, healed with a large callus formation.

Figure 12: ATT fracture

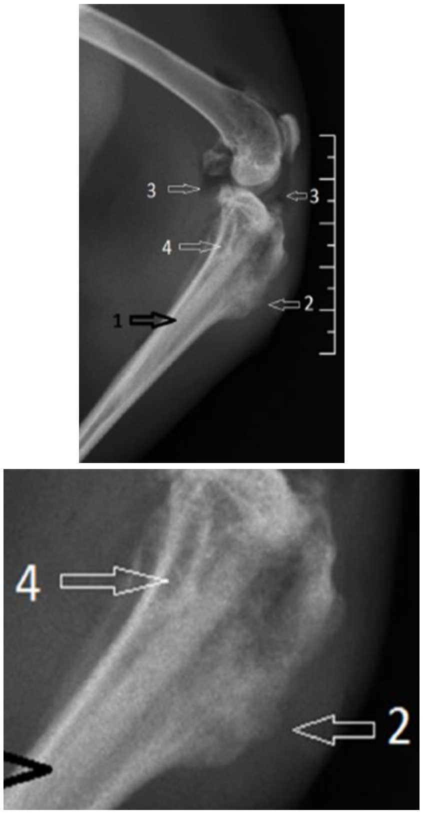

Figure 13: Accidental fracture

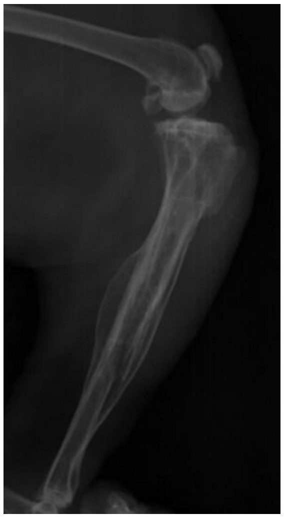

Histological results

Callus formation

Figure 14 shows a section from ATT callus, Hematoxylin-Eozine dye, magnitude 10X10. Bone tissue with nonuniform disposition, viable osteoblasts, with present intra-cytoplasmic nucleus and cartilaginous areas with chondroblasts with intracytoplasmic visible nuclei are observed, specific to bone callus formation. Figure 15 shows an overview of bone callus, Hematoxylin-Eosin dye, magnitude 4X10, from the accidental fracture callus site. Bone areas are irregularly arranged, alternating with cartilaginous areas, image of bone remodeling, specific to bone callus such as in Figure 14. Figure 16, is a detailed image of bone callus remodeling process, Hematoxylin-Eosin dye, magnitude 40X10, digital zoom. Multinucleate osteoclasts are visible, no 1, surrounded by bone tissue, with viable osteoblasts, intracellular nucleus visible, no 2. Figure 17 shows bone callus from the control specimen, Hematoxylin Eosin dye, 4X magnification. Bone remodeling areas are identified, being visible osteoclasts surrounded by newly formed bone tissue, with viable osteoblasts, similar to the previously presented samples.

Figure 14: ATT fracture

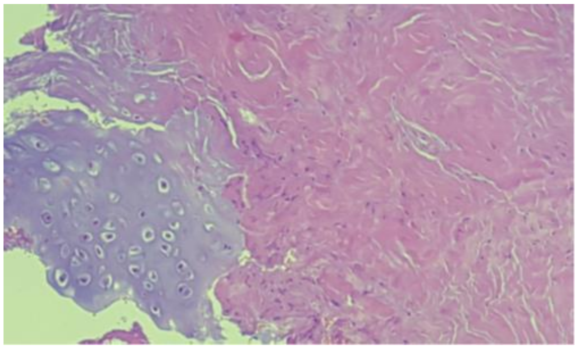

Figure 15: Accidental fracture callus

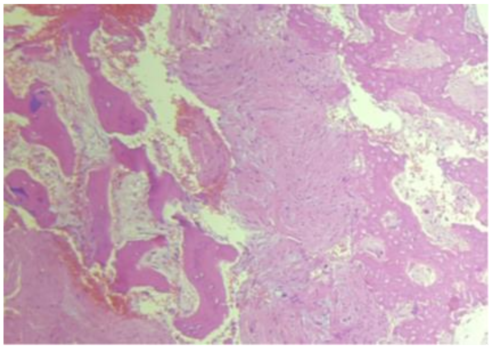

Figure 16: Bone remodeling

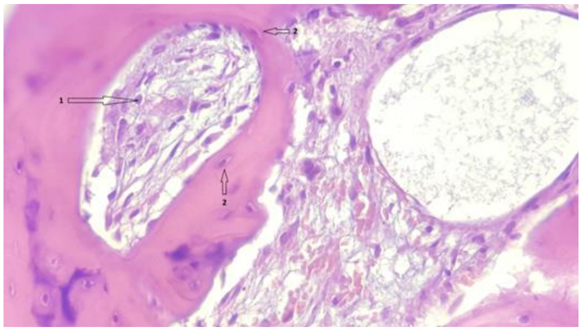

Figure 17: Control specimen callus

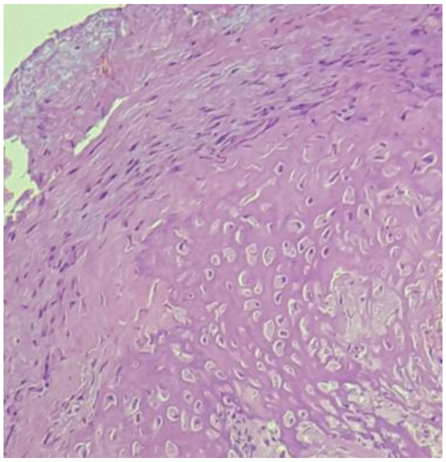
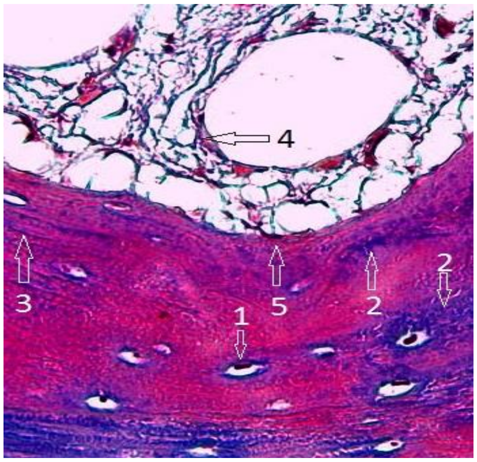


Bone alloy interface, it is showed in Figure 18, Tricrome Masson dye, magnitute 10x40. In this section we highlight viable bone cells, with intracytoplasmic nucleus, number 1 and collagen fibers, colored in blue, noted with no 2, arranged both pericellularly and in bone mass, sign of osteoblastic activity.The Mg-1Ca alloy, noted with no 4, which is in the process of resorption, is directly adherent to the bone surface, without identifying interposing tissues at the bone-alloy interface, no 5. In the immediate vicinity of the implant, the bone tissue is disposed in parallel lines, no 3, remineralization sign, bone formation.

Figure 18: Bone tissue and Mg-1Ca alloy, 6 weeks, Tricrome Masson dye



Vital organs

Figure 19 shows a section through the lung tissue. The alveoli appear in the form of empty spaces, marked with number 1. No intra-alveolar secretions or alveolar collabs are observed. Interstitial spaces, marked with no 2, have a normal appearance, without interstitial infiltration. A bronchioleis marked with no 3, with normal appearance and structure, and blood vessels are identified with no 4. No signs of gaseous embolism are observed.

Figure 20 shows a section through the renal tissue. It looks normal, with no pathological signs. The glomeruli of normal appearance and structure are marked with number 1, and with number 2 the collecting channels.

Figure 21 shows a section through the liver tissue. Liver cells, marked with number 1 have a viable appearance, with a visible nucleus inside. These are placed in columns delimiting the biliary drainage channels, marked with no 2. The tissue, does not have pathological aspects.

Figure 19: Lung, 6 weeks

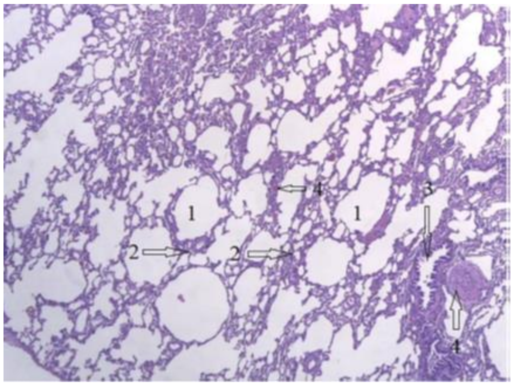


Figure 20: Kidney, 6 weeks

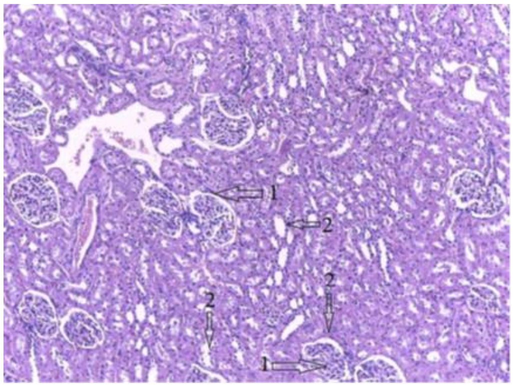

Figure 21: Liver, 6 weeks

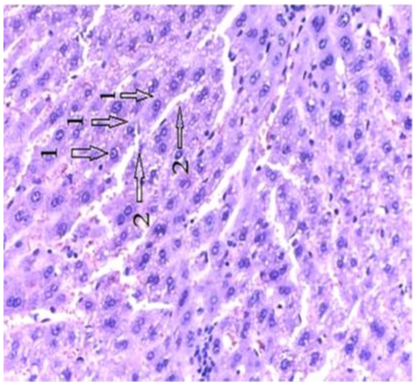

Blood tests results

The values obtained by monitoring the physiological blood parameters, preoperatively and at 6 weeks, are summarized in the following Table and Figures 22-25.

Table 3: Ionogram evolution

No	Magnesium (mg/dL)		Calcium (mg/dL)		Sideremia (µg/dL)		Sodium (mmol/L)		Potassium (mmol/L)	
	Preop	6 week	Preop	6 week	Preop	6 week	Preop	6 week	Preop	6 week
1	2.41	2.72	14.75	13.75	185.51	180.2	146.31	151.8	7	3.43

Figure 22: Mg evolution

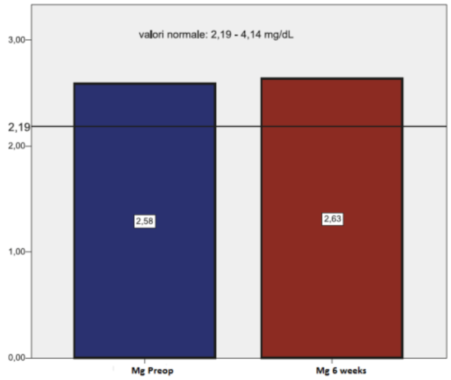

Figure 23: Ca evolution

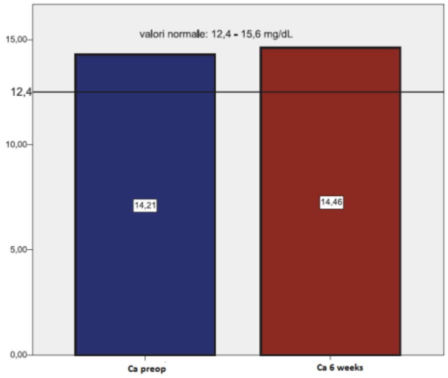

Figure 24: Na evolution

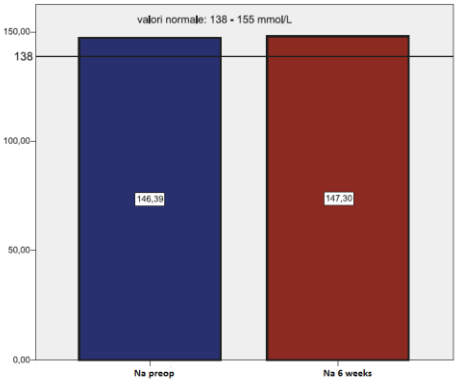

Figure 25: K evolution

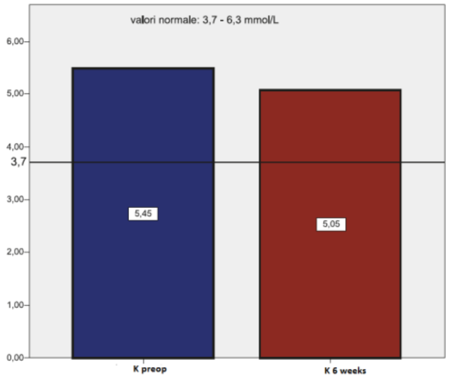

The studied parameters, magnesium, calcium, sodium and potassium, had registered average values preoperatively and at 6 weeks, within the range of normal, physiological values, characteristic to their species.

Urea has a slightly higher preoperative mean value than normal, 24.09 mg/dL compared to 23.50 mg/dL, but at 6 weeks we recorded an average value of 23.35 mg/dL, which is within the the normal, physiological limits of the species.

Creatinine has a preoperative mean value of 0.73 mg/dL and 0.74 mg/dL at 6 weeks, both values being within normal range.

Regarding the evolution of hepatic function indicators, both ALT and AST have preoperative average values and at 6 weeks, within the normal range, being from 25.8 IU to 23.2 IU for ALT and from 23, 3 IU to 24 IU.

Table 4: Vital organ function evolution

No	Serum urea (mg/dL)		Creatinine (mg/dL)		ALT (µg/dL)		AST (mmol/L)	
	Preop	6 week	Preop	6 week	Preop	6 week	Preop	6 week
1	16.7	17.2	0.56	0.59	21	23	22	23

DISCUSSIONS

In vivo studies represent a superior stage of research required to certify the results obtained through in vitro studies. The present study, in vivo, performed on laboratory animals, rabbits, aimed at evaluating the biocompatibility of a Mg-1Ca binary alloy by evaluating the influence on the formation of bone callus, cell viability and systemic effects, impairing the function of vital organs.For this, we radiologically followed the evolution of the implant and the adjacent bone, we performed blood tests and histological sections

In the radiological images obtained, we notice callus formation both, at the level of the experimental fracture and in accidental fracture, at6 weeks after surgery. No radiologically transparent lines were identified at the bone implant interface, suggesting that there is no local osteolytic process or development of fibro-cartilaginous tissue at the bone implant interface. This observation suggests that the biodegradation process of the Mg-1Ca alloy does not adversely interfere with the biological process of bone tissue formation.

Histological examination is an important element in determining the biocompatibility of the Mg-1Ca alloy. Sample collection was performed at 6 weeks postoperatively.

The histological sections made from the samples collected from the fracture zone adjacent to the Mg-1Ca alloy implant, confirm the formation of the bony callus, showing areas of endochondral ossification, newly formed bone with disordered disposition, areas of bone remodeling, in which many osteoclasts and osteoblasts are identified. We can notice a cellularity specific to the formation of a normal bone callus, with no tissue necrosis. The trichrome Masson sections, shows a normal bone development with newly formed bone tissue at the alloy interface.

In the sections harvested from the vital organs, no pathological changes are observed.

This observations suggests that the biodegradation process of the Mg-1Ca alloy does not interfere negatively with the biological process of bone formation, allowing the formation of the bone callus in the fracture site, in a normal time period.

The study of blood parameters plays an important role in evaluating the systemic effects of the corrosion process of the Mg-1Ca alloy. Magnesium and calcium release from the alloy during the corrosion process did not lead to pathological changes in the serum values of the two ions. At the same time, we do not encounter pathological changes in serum sodium and potassium, ions with a very important physiological role.

Renal function is not influenced during the corrosion process, which is supported by the evolution of urea and creatinine values. Similarly, the liver function was normal, during the study, the ALT and AST transaminases recording average values within normal limits, at both evaluation times.

These data do not confirm the suspicion of pathological changes induced by systemically released corrosion products and gas embolism in vital organs.

The shape of the implant (pin) is basic, but reproducible; 3D printing of a patient-specific bioresorbable implant may be an option, as in modern knee surgery [16].

CONCLUSIONS

Thus, as a final conclusion, I can say that the Mg-1Ca alloy has been proven to be:

- Safe, with a high degree of biocompatibility
- It shows good capacity for osteointegration and osteo-conductivity
- With no local toxic effects, no impairment with bone callus formation
- No systemic toxic effects, no impairment with vital organs function
- A promising future solution for orthopedic surgery.

Military psychological distress-virtues model

Azizeh Alizadeh[1], **Seyed H. Salimi**[2]

Abstract: *Background and Aim: Military personnel, parallel to appropriate personality traits to the military environment, need virtues and character strengths(CS) that contain values appropriate to the environment. We designed a model that examines the impact of comprehensive virtues and CS in reducing psychological distress.*

Methods: The present study is an SEM study. The sample community is an available example of 410 persons of military men in Tehran. We used a demographic information questionnaire, Kessler Psychological Distress Scale (K-10), and Virtues Inventory in Action (VIA-120).

Results: findings showed virtues and CS of wisdom, justice, humanity, and transcendence (except for spirituality) are significantly related to psychological distress. With increasing CS, psychological distress in employees decreased, but with increasing virtues, psychological distress in employees increased. The virtues and CS of temperance and courage were not significantly associated with psychological distress.

Conclusions: According to the results of this study, military services should pay more attention to the virtues and CS effective in reducing staff distress and strengthening these traits in them.

Keywords: *Military personnel, Psychological distress, Virtues, Character Strengths*

INTRODUCTION

Psychological distress is a mental health outcome embodied by psycho-physiological and behavioral symptoms that are not specific to a given mental pathology. It includes symptoms of anxiety, depressive reactions, irritability, declining intellectual capacity, tiredness, sleepiness, and may lead to premature morbidity and mortality and Low-efficiency organizations [1]. A review of texts related to the psychological distress in military personnel showed that studies conducted in this area are more focused on personality traits and behavior. Such as hardiness and adjustment [2], sleep, resilience [3], perceived support, substance use, suicidal ideation [4], self-compassion and morale injury [5], negative life events [6], and like that. In military psychology, analytical and practical intelligence, motivational factors, and personality (for example that low conscientiousness and high extraversion in the big 5-personality model) are considered a predictor of the outcomes of performance in military colleges. Personality is about differences between individuals and how one reacts to circumstances, but these characters do not address values and have limitations in predicting successful military personnel [7]. So, other variables have been incorporated into the network of predictive variables because of theoretical advances in military psychology and the evolution of the institutional function of the military [8]. One of that is positive military psychology with the assumption that the military being a positive institution consists of

pathology-free mentally and physically fit soldiers who share positive traits, positive emotions, and positive relations. Therefore, it is imperative to identify, nurture and optimize all those positive aspects of a soldier which can strengthen him for better operational effectiveness, adjustment, and optimal functioning [9]. According to positive military psychology, Virtues and strengths can be more suitable predictors for successful military personnel and institution [7]. Military doctrine has affirmed that character and values are critical for successful military environments [10]. An individual expresses his or her values through one's CS. This has been found to play an important role in leadership, adaptability, and achievement [11]. Therefore, CS is an important factor for being resilient applicants to high-risk organizations [12].

A soldier must not only have the courage and aggressiveness for combat operations but also cultivate the empathy and compassion necessary to treat noncombatants and enemy prisoners humanely [13]. In addition, virtue ethics as being the best way of enhancing the chances of soldiers behaving morally because the rules or codes of conduct imposed from above, lack flexibility, and leave less room for personal integrity. changes in the military’s environment have led to a shift from traditional tasks to more complex tasks, and especially in today’s missions, one could expect that the proper virtues are not solely the martial ones [14].

Gordon Alport’s theory argued that character belonged to philosophy and not psychology, and denied any connection between the character's strengths and the personality concept. Later, Peterson and Seligman´s research on positive psychology from 2004 sparked a renewed interest in the concepts of character and CS (15). Peterson and Seligman formulated a taxonomy of 24 “CS within six different virtues” based on Confucian, Taoist, Buddhist, Hindu, Greek, Judeo-Christian, and Muslim writings concerning virtue [16].

Wisdom and knowledge – cognitive CS that entail the acquisition and use of knowledge (creativity, curiosity, open-mindedness, love of learning, perspective), Courage - emotional CS that involve the exercise of will to accomplish goals in the face of opposition, external or internal (authenticity, bravery, persistence, zest), humanity – interpersonal CS that involve tending and befriending others (kindness, love, and social intelligence), justice – civic CS that underlie healthy community life (fairness, leadership, citizenship), temperance-CS that protect against excess (forgiveness, modesty, prudence, self-regulation) and Transcendence – CS that forge connections to the larger universe and provide meaning (appreciation of beauty, gratitude, hope, humor, spirituality) [17].

CS are personality traits that are positively valued, and represent different routes to the superordinate virtues [18]. The relationship between virtues and PTG in different countries demonstrated these three virtues (Interpersonal, Vitality, and Cautiousness) were positively related to life with satisfaction and flourishing, as well as negatively related to depression, anxiety, psychological distress, and pathology Internet use [19].

A review of the literature on virtues and CS showed that many studies have been done on the relationship between psychological well-being and virtues. We found no study to examine the role of a complete list of virtues and character strength in causing psychological distress. More subjective/ psychological well-being can be achieved by applying CS [20].

Studies explored a significant positive relationship between the three virtues (Interpersonal, Vitality, and Cautiousness) and life satisfaction [21] and psychological well-being and enhanced mental health among diverse populations in western and eastern cultures. In a study, CS use is a unique predictor of subjective well-being, but not the health-related quality of life. The VIA strengths of hope and zest were significant positive predictors of life satisfaction [22].

A Structural equation modeling study that specifies the predictive effects of some CS (Seven CS of critical thinking, emotional intelligence, gratitude, forgiveness, hope, spirituality, and zest) in a depression on individuals with major depression, demonstrated an indirect effect on depression through the mediation of dysfunctional attitudes, negative affect, and happiness. CS had negative effects on dysfunctional attitudes and positive effects on happiness [23].

According to Leontopoulou & Triliva (2012), Wisdom, courage, and transcendence were each highly and positively correlated with the wellbeing subscales of environmental mastery, purpose in life, and self-acceptance. Good physical and mental health were positively predicted different aspects of wellbeing and CS; nevertheless, mental health was a stronger predictor of wellbeing and CS than physical health.

Positive psychology interventions that involve the enhancement of strengths are found to increase well-being and decrease depression effectively, as suggested by a meta-analysis of 51 studies (Sin and Lyubomirsky, 2009). Indeed, empirical findings suggest that having a good character through the use of strengths is inversely related to depression, suicidal ideation, and substance abuse, whilst the use of strengths can have a buffering effect against stress, reduce the disability caused by mental disorders and contribute to their prevention. Wright and Lopez (2005) proposed that strengths constitute important resources for mental health improvement and as such their enhancement should be incorporated into the health and well-being interventions [24].

Based on an international sample of 238 adults, general CS underuse and overuse were related to negative outcomes, while optimal use was related to positive outcomes. The overuse of social intelligence and modesty, and underuse of zest, humor, self-regulation, and social intelligence were associated with social anxiety. Using discriminant analysis, this combination successfully resorted 87.3% of the participants into those that do and do not have clinical levels of social anxiety. These findings suggest that strengths are multifaceted, providing novel insight into the role that sub-optimal-use facets play in undesirable outcomes, providing a glimpse of psychopathology through the lens of positive psychology [25].

Exploring psychological distress through the lens of virtues and CS allows for understanding individual differences and kinds of virtues and characteristics that help decrease psychological distress in people. As mentioned, we did not find a comprehensive study that examines the wide range of negative emotions (distress) based on all the virtues and strengths. Studies have focused more on the role of some of the strengths and ignored the role of the six virtues of Seligman and Patterson. The concept of psychological distress without any diagnostic label can help identify and assess people at risk for psychological problems. Therefore, the authors decided to examine the role of each of the virtues and characteristics in reducing psychological distress. The purpose of this study is to investigate the model of psychological distress based on virtues and CS.

METHOD

The present study is a cross-sectional study. The sample community is an example of all the military men in Tehran. Sample in the present study, the military organizations of Tehran have been selected by available sampling. The sample size in this study is 384 people, which has been done by available sampling based on the Cochran sample size formula:

$$n=\frac{Z^2\,pq}{d^2}$$

In this formula: z= 1.96; p = q = 0.5; and d (error value) = 0.05. To compensate for possible errors and increase the test power, the sample size was increased by 410 units [26].

Demographic information questionnaire: This questionnaire will be designed by the researcher and includes information such as age, education, work experience, marital status.

Kessler Psychological Distress Scale (K-10): The Kessler Psychological Distress Scale (2002), identifies mental disorders in the general population. Questions on this scale are scored as a Likert scale from always (0) to never (4). This scale doesn’t target a specific psychological disorder, but generally, identify the level of anxiety and depressive symptoms that a person has experienced over the past few weeks. Various studies have shown that the K-10 questionnaire has good validity and reliability. Studies on K-10 show a strong correlation between high scores on the Kessler Psychological Distress Questionnaire and the diagnosis of mood and anxiety disorders by the International Composite Diagnostic Interview Form (CIDI). There is also a less but significant relationship between questionnaire scores and other psychiatric disorders [27].

Virtues Inventory in Action (VIA-120): Seligman and Patterson prepared a short form of 120 that includes 6 virtues of wisdom, courage, humanity and love, justice, temperance, and transcendence. Each of the moral virtues contains several CS that is measured by 5 questions, and are complemented on a Likert scale from very similar to me (5) to opposite to me (1), and dimensionally each point Show the strength of character. The 120-item scale is fully consistent with the original English form VIA-240 in terms of reliability, validity, and factor structure [28]. The reliability and validity of this scale were assessed and confirmed by Namdari [29].

RESEARCH PROCESS

To implement the questionnaires, first, the necessary permits were obtained from the relevant centers and then the command of each unit was coordinated. Questionnaires were distributed among the staff and the necessary explanations were given on how to answer and confidentiality of the answers. After completing the answer, questionnaires were collected.

Result

Descriptive findings of demographic variables showed the mean and standard deviation of the age and work experience (years of work in the organization) of the participants, respectively are 36.72± 7.02 and 17.35±6.19. In addition, 20% were married and 30% were single. 32% had one child, 20% had two children and the rest had more than two children. Almost 14% had a diploma, 56% had a bachelor's degree, 20 % had a master's degree, and 10% had a doctorate. 60% worked in the morning shift, 30% in variable work shifts, and 10% in the evening shift.

Measurement Model

In measurement model a): Internal consistency (Cronbach's alpha and Composite reliability), convergent validity (Indicator reliability, Average Variance Extracted) (in Table 1), and discriminant validity were suitable. According to Table 1, all values CR and AVE are in the appropriate ranges. Discriminant validity showed that all variables had appropriate HTMT. Also, according to the Fornell-Larcker scale, each variable had more variance in common with its variable than the other. In Figure 1 the model of psychological distress of military personnel based on the virtues and CS is shown.

Table 1: Cronbach's alpha, Composite reliability and Average Variance Extracted for virtues and CS

Virtues (second order variables)	CS (First order variables)	Cronbach's alpha	CR	AVE
Wisdom	----		0.893	0.736
Wisdom	Creativity	0.618	0.796	0.566
	Curiosity	0.706	0.819	0.532
	Open-mindedness	0.700	0.816	0.529

	Modesty	0.534	0.763	0.517
	Prudence	0.716	0.824	0.54
	Self-regulation	0.401	0.765	0.621
Transcendence	----		0.955	0.782
	Appreciation of beauty	0.668	0.818	0.601
	Gratitude	0.753	0.835	
	Hope	0.769	0.839	0.511
	Humor	0.755	0.835	0.506
	Spirituality	0.821	0.873	0.579

Table 2 shows path coefficients of virtues and CS with the psychological distress of military personnel. According to this table, virtues, and CS of wisdom, justice, humanity, and transcendence (except for spirituality) are significantly related to psychological distress. With increasing CS, psychological distress in employees decreased, but with increasing virtues, psychological distress in employees increased. The virtues and CS of temperance and courage were not significantly associated with psychological distress.

The most common measure used to evaluate the structural model is value R2 and Stone-Geisser's Q^2. The value of R2 equal to 0.75, 0.50, or 0.25 for the endogenous latent variables can be described as a general rule as strong, moderate, and weak, respectively. For Stone-Geisser's Q^2 if the value of Q2 for an endogenous structure achieves three values of 0.02, 0.15, and 0.35, it indicates the weak, medium, and strong predictive power of the structure with its related exogenous structures [30]. Table 3 shows these values for virtues and CS.

Table 3: Values of R^2 and Q^2 for virtues and CS

Virtues (second-order variables)	CS (First order variables)	R Square	R Square Adjusted	Q^2
Wisdom	----	0.78	0.78	0.27
	Creativity	0.74	0.74	0.34

DISCUSSION

Findings of this study showed, the CS of wisdom, including, creativity, curiosity, love of learning, open-mindedness, perspective, played a mediating role in reducing psychological distress. The research literature is consistent with our findings. Creativity led to looking at problems from different perspectives, establishing new solutions and connections, flexibility in the thought process, increasing their connection to the unknown [31], brainstorming phenomenon, and reducing workplace stresses [32]. Studies show that curiosity and open-mindedness with the tendency to tolerate potentially different opinions [33], new knowledge and information, the choice of diverse and different perspectives, the ability to use a balanced and objective mentality when participating in problem-solving [32]. Open-minded people think logically because they can accept all possible logical perspectives and come up with a better solution [34]. Curiosity with openness to the experience is associated with self-regulation, cognitive development, school and university learning, job performance, interpersonal communication, personal growth, and well-being [35].

In this study, justice's CS, including citizenship, fairness, and leadership had a significant role in reducing distress. "good citizens" have higher levels of social trust and a more positive view of human nature, score low on alienation and ethnicity [36], organizational citizenship behavior is likely to be formally associated with organizational rewards and helps the organization promote a positive social and psychological climate. Beyond their duties, employees find it more attractive to engage and inform about the organization, to talk and encourage others, to volunteer to take on additional responsibilities in the workplace, with the help and guidance of co-workers [37]. Also, supervisor-nurse relationships, teamwork, and wellbeing explain almost half of the nurses' commitment to the hospital, as well as half of the intention to leave the hospital [38]. About fairness, people with higher fairness in career advancement show more parental role, respect, and commitment to others, care, and understanding in relationships [36]. Employees' perceptions of fairness lead to more positive variables such as job satisfaction, organizational commitment, productivity, and organizational citizenship behavior, work results, or attitudes and work behaviors [39]. Also, according to Seligman and Peterson (2004) people with leadership power are more likely to be promoted in their jobs and feel more well-being [36].

In addition, findings of this study indicated a significant role of transcendence CS (except spirituality) including appreciation of beauty, hope, humor, and gratitude with psychological distress. The use of these CS led to reducing psychological distress. This finding is consistent with the research literature. Research has shown that appreciation of beauty is positively correlated with openness to experience, extraversion, and agreement [40], life satisfaction, positive impact, and post-traumatic growth [41].

Depression was negative and gratitude was a positive predictor of psychological well-being [42], and negatively related to several negative emotional [43]. Also, expressed higher mood gratitude with fewer depressive symptoms, and PTSD. About humor, higher levels of humor were associated with fewer depressive symptoms [44] low anxiety and depression, and anti-production behaviors in the workplace, and increased organizational citizenship behaviors, moderating role between organizational stressors and organizational citizenship behaviors. The use of humor leads to mental flexibility and intellectual stimulation and reduces the threat by restoring the situation against the destructive effects of stressors [45]. Our findings showed spirituality had not been significantly associated with psychological distress. Spirituality is positively associated with happiness and meaningful living. Many studies have shown that spirituality and religiosity are more closely linked to greater physical and mental health. For example, a meta-analysis concluded that more religiosity was associated with fewer depressive symptoms, with no evidence that age, gender, or ethnicity influenced the relationship. According to Einsliecht et al., belief in religion modulates anxiety [8].

Also, our study showed there is a positive and significant relationship between CS of love and humanity including kindness, love, and social intelligence, and psychological distress. This result is consistent with the literature. In the study of the effect of parental attachment and the language of love on resilience, it was found that secure attachment and receiving love from parents lead to more resilience. Parents' loving language, affirmative words, and supportive actions significantly build resilience by creating emotional, motivational, and practical resources [46]. The results of a study showed that spiritual care with the faith-hope-love model has had positive results for the patient [47]. Also confirmed that there is a significant relationship between health and love and faith. Multidisciplinary research evidence argues that different religions have one thing in common, at least in terms of one main message: that life means loving one another. The definition of love, in its essence, is an expression of generosity and altruism. Likewise, love can influence not only positive psychology and existentialism but also the fanatical and fundamentalist views and practices that still exist in the world today [48]. Regarding social intelligence, the results of a study showed that social intelligence can protect young people from the psychological damage of being victimized by peers [49]. Findings [50] showed that there is a significant relationship between social intelligence and depression. Also, a significant relationship was found between social skills and social awareness, but no statistically significant relationship was observed between social information processing and the level of depression. Also, important relationships between social desirability and social intelligence in smoking status have been found [51].

Other CS in the virtues of courage (courage, originality, perseverance, and vitality) and temperance (forgiveness, modesty, prudence, and self-regulation) were not significantly associated with psychological distress. The results of the most relevant research showed that each of these positive characteristics can affect psychological well-being and positive emotions and results. Research in these studies has shown, for example, that high self-control leads to thought control, emotion regulation, psychological well-being, greater academic achievement, better interpersonal relationships, and ultimately greater adaptation and low self-control, in contrast to many social problems, obesity, and Drug use, crime, shopping, and procrastination [52]. The constructive relationship between forgiveness and health through direct mechanisms may be accomplished by controlling the cognitive process of rumination, and the resulting negative emotions, such as anger or resentment or indirect effect, may be mediated through distinct variables such as health behavior, performance between Individuals develop social support and mental health and are associated with low suicidal behavior and depressive symptoms [53]. We reason that the virtues of temperance and courage and the CS of them, can logically and intuitively be incorporated into the nature of the military job and be considered as an inseparable feature of this job. Therefore, increasing it cannot affect reducing psychological distress.

In the present study, all six virtues (significant including wisdom, justice, and transcendence) and non-significant (humanity, courage, and temperance) were positively associated with psychological distress. That is, with the increase of these virtues, the level of psychological distress of the employees increased. The positive association of virtues with psychological distress is a strange consequence, given that according to Seligman and Peterson, virtues lead to well-being and ultimately self-fulfillment [36]. Based on our hypotheses, the relationship between virtues and psychological distress was expected to be negative. According to these findings, while the results of the first-order variables of CS were negative with psychological distress, but the increase in the virtues of wisdom, humanity, justice, and excellence in the sample led to more distress and suffering. According to Rosch et al. (1976), CS has a "natural classification" that manifests itself in practice conveniently and clearly. Experimental studies support this idea and show that cognitive processes also have a more specific efficiency when they have a primary and natural surface content. While CS at the abstract levels is called virtues and their performance is more complex [36]. According to early texts in this field, if we consider distress or suffering as opposed to happiness, any person who has a virtuous life will be happy. But according to Bloomfield, virtue does not guarantee happiness, and the ethics of virtue involves worries about oneself and others [54]. Suffering is included in the theoretical framework of virtue and is an inseparable part of virtue. Virtues have the appropriate structure to maintain different types of values. The connection between suffering and virtue already exists in the history of philosophy and theology, albeit sporadically. Suffering plays a key role in the proper functioning of groups or groups and their wisdom. In addition, suffering is very important in a group or social virtues such as justice and love and individual virtues such as faith [28].

Limitation

Our sample in this study included only men. These people mostly had administrative work and were somewhat away from the hardships of military life, such as being sent to war zones. Of course, they experience some limitations and difficulties of working in military services.

CONCLUSION

According to the results of this study, military organizations should pay more attention to the ethical virtues effective in reducing staff distress and strengthening these traits in individuals.

Ethical considerations

This article is a part of a doctoral dissertation approved with IR.BMSU.REC.1399.341 Ethics Code. The online version of the application is available at the following address and is open to the public: https://ethics.research.ac.ir/IR.BMSU.REC.1399.341. Target individuals were informed about the purpose of the study and their right to withdraw from the study at any point. Participants were free to withdraw from the study at any point. All interviews were kept confidential.

Modern methods to differentiate benign thyroid nodules from malignant ones

L. Eftimie[1,2,3], R. Hristu[2], M. Dumitrescu[1], M. Costache[3], S.G. Stanciu[2], M. Sajin[3], G.A. Stanciu[2]

Abstract: *Objective: The purpose of this study is to compare the capsular structure appearing in follicular adenoma and papillary thyroid carcinoma to differentiate the benign and malignant thyroid nodules.*

Methods: Second Harmonic Generation (SHG) Microscopy was used to image collagen distribution in the capsules of several types of nodules. The tissue fragments were formalin-fixed, paraffin-embedded but without H&E staining, with 4-5 microns thick sections. From the same sample, two consecutive sections were made. The first was colored with H&E and capsule images were acquired with an optical microscope. The second was not colored with H&E. On the uncolored sample, type I collagen from the capsule was visualized by SHG microscopy. In addition, a parameter was used to study the orientation of collagen fibers, obtained from the Fast Fourier Transform (FFT) analysis of 2D-images.

Results: SHG microscopy images were acquired to assess the collagen organization of tumoral capsular thyroid nodules previously diagnosed as benign or malignant by conventional H&E staining. Different degree of collagen fibers orientation was observed from the two kinds of capsules and quantified using FFT analysis.

Conclusion: These above described microscopy method can be used to distinguish between benign and malignant thyroid nodules, based on different degree of the capsular collagen fibers orientation.

Keywords*: follicular adenoma, papillary thyroid carcinoma, benign and malignant thyroid nodules, capsular collagen fibers*

INTRODUCTION

The clinical and imagistic diagnosis of malignancy must be confirmed in pathology departments.

Although histopathology and cytopathology are the main tools for diagnosing cancer, there are some dificult cases that pathologists may encounter during routine diagnosis procedures, where the differentiation between a benign tumor proliferations from a malignant one is very difficult to achieve. In such situations complementary examination procedures are required (eg. serial sections from formalin-fixed, paraffin-embedded tissue blocks, mounted on glass slides and usual stained with H&E, immunohistochemistry, molecular studies, electron microscopy, etc.).

Another method which can be used in thyroid pathology for diagnostic purposes is Second Harmonic Generation (SHG) Microscopy.

SHG microscopy is a label-free laser scanning

[1] Department of Pathology, Central Military Emergency University Hospital “Dr. Carol Davila”, Bucharest

[2] Center for Microscopy-Microanalysis and Information Processing, University "Politehnica" of Bucharest, Romania

[3] Department of Pathology - University of Medicine "Carol Davila" Bucharest

microscopy technique that exploits a nonlinear optical effect – the generation of the second harmonic in samples illuminated by an intense laser field [1, 2]. SHG can occur only from materials that do not have a center of symmetry, thus analyzing absolute molecular structure in organized organic environments, such as collagen fibrils, microtubules and the myosin chain of muscle cells. SHG microscopy has been proven to be a useful tool in biomedical tissue imaging [2] because it can be used for imaging endogenous structures like type I collagen [1] as well as for the characterization of collagen organization [3-5] and has been recognized as a promising approach for the diagnostics of different cancer types [6-8], by detecting collagen structure modifications [7].

The thyroid gland is wrapped in a thin fibrous capsule, from which originate numerous fibrous septae that penetrate the thyroid parenchyma and divide it into incomplete lobules (the so-called thyromeres). Macroscopically, the thyroid capsule seems complete, but it is incomplete from the microscopic point of view, as it adheres tightly to adjacent structures (laryngeal thyroid cartilage and trachea) [9].

Nodular enlargement of the thyroid gland comprises those situations in which one or more nodules are present. This presence of nodular enlargement is the most common in the case of non-toxic nodules, also known as adenomatous goiter or colloidal goiter.

Polinodular goiter with different-sized follicles can be a clinical manifestation of a wide range of different pathologies and not the expression of a single disease [10].

The usual classification of neoplasms of follicular epithelial cells are in benign (adenomas) and malignant (carcinomas) tumor proliferation. The benign ones are called follicular adenomas [11], which are encapsulated, non-invasive tumors showing evidence of thyroid follicular cell proliferation without the specific nuclear characteristics of thyroid papillary carcinoma [12].

Papillary Thyroid Carcinoma (PTC) is a malignant epithelial tumor, usually invasive, showing evidence of abnormal proliferation of thyroid follicular cells with characteristic nuclear changes: irregular contours and nuclear pseudoinclusions, nuclear membrane irregularities, and chromatin marginalization. For a correct diagnosis of the classical PTC, the papillary fibrovascular axes, the invasive character or the characteristic cytological features are required. [12].

The encapsulated variant of PTC is a type of proliferation with typical cytological and architectural changes, entirely surrounded by a thin, fibrous capsule that may be intact or infiltrated only focally by the tumor. If the capsule is invaded by the proliferation of malignant tumors, we are dealing with an aggressive form of PTC.

The encapsulated variant represents about 10% of all cases of PTC and has an excellent prognosis. Differential diagnosis is made with follicular adenoma with papillary hyperplasia [12].

Over the years, diagnostic criteria for follicular and papillary thyroid carcinomas have changed, but the two names have been retained. There have been several variants of papillary carcinoma for which the primary diagnostic criterion is based on nuclear features [11].

Some thyroid encapsulated neoplasms may present diagnostic difficulties due to the fact that only nuclear changes are sufficient to justify and diagnose PTC but there is the uncertainty about the capsular or vascular invasion. Encapsulated follicular tumors lacking the PTC nuclear characteristics are difficult to differentiate. For example, follicular carcinoma (a malignant tumor) can be distinguished from follicular adenoma (a benign tumor) only by demonstrating invasive character in the nodule capsule or capsular vessels [12].

We started from the idea that SHG can be used to observe three-dimensional structures of a tissue sample without the need for staining.

In this way, this method helps us in the correct diagnosis of encapsulated tumor entities that require complementary examinations from the pathologist or in order to determine a possible capsular structural change before the onset of malignant transformation of a benign encapsulated tumor.

OBJECTIVE

The purpose of this study was to use the collagen structure in the nodule capsule to obtain information on the follicular adenoma capsule and encapsulated papillary thyroid carcinoma (PTC) capsule for differentiating between benign and malignant thyroid nodules. The study was based on optical microscopy images and SHG microscopy, with the latter used for the visualization of type I collagen. We also show that the FFT analysis of the SHG images can provide information about the collagen fiber orientation.

MATERIALS AND METHODS

A batch composed of encapsulated-PTC and follicular adenoma tissue from 24 sections tissue samples (12 for Encapsulated-PTC capsules and 12 for follicular adenoma capsules) was used for this study. Sections of 4-5 µm were made from each paraffin tissue block. They were mounted on glass blades and stained with Hematoxylin and Eosin (H&E) and visualized with a light field microscope (Leica DM3000). The tissue architecture of the normal, benign and malignant regions of interest and the capsule surrounding the nodules have been identified. Unstained pairs of the H&E stained tissue sections were used for SHG imaging for collagen organization assessment.

SHG imaging was performed using a Leica TCS-SP confocal laser scanning microscope modified for nonlinear optical imaging [13]. We have used a mode-locked Ti:Sapphire laser operating at 780 nm and with ~150 fs pulses. A 40X, 0.75 numerical aperture objective was used to focus the laser beam on the sample, while the SHG signals were collected in the forward direction through a condenser lens. The average power reaching the sample plane was kept less than 15 mW and no photodamage was observed on the samples.

SHG images were used to estimate the collagen fiber orientation by FFT analysis using ImageJ software. For an image containing aligned fibers, we expect an FFT image with higher values along the direction orthogonal to the direction of the fibers and with an elliptic intensity plot. On the other hand, for an image with randomly oriented fibers, the FFT image intensity plot should be close to a circle. The FFT power spectra images were first binarized and then fitted with an ellipse. A collagen orientation index was calculated based on the length of the minor (S) and major (L) axes of the ellipse: $N = 1 - S/L$ [14]. Collagen orientation can thus be represented by an index ranging from 0 (random fibers) to 1 (aligned fibers).

RESULTS

Optical microscopy images of H & E stained sections do not give us information about the ultrastructure of the studied tumoral nodules capsule. The capsule appears as a fibrous structure surrounding the tumoral nodule. It looks identical to the follicular adenoma nodule and to the Encapsulated-PTC nodule. So this optic method is limited in terms of capsule study.

On the other side, the SHG helps to study the ultrastructural changes of the capsule. SHG highlights type I collagen in the capsule structure. So we can see if there are qualitative changes of this type of collagen from the two kinds of capsules. In addition, using FFT analysis of SHG images we can bring precious differentiation information of the two types of capsules: the follicular adenoma nodule or the Encapsulated-PTC nodule. We have noticed that in the Encapsulated-PTC nodule capsule there appears to be a collagen fiber organization as if they were trying to isolate malignant epithelial proliferation.

We acquired images with Second Harmonic Generation Microscopy which were used to assess the collagen orientation of tumoral capsular thyroid nodules previously diagnosed as benign or malignant by conventional H&E staining.

We compute the FFT spectra for the SHG images acquired for the considered pathologies. One can see that the average collagen orientation (N) computed from the FFT spectrum is higher for the follicular adenoma capsule ($N = 0.69$) than for the encapsulated-PTC capsule ($N = 0.4$). The FFT spectra were calculated for the entire images. We consider that if the spectra are computed for smaller regions of interest (ROIs), a distribution of values can be obtained, depending on the degree of alignment for the collagen fibers in the considered ROI. Averaging over a larger area, which is also the case of the whole area analysis, it results in a lower N. Even though N was calculated on whole areas, the obtained results show a difference in collagen organization between the two capsules.

CONCLUSIONS

We found differences in the orientation of collagen fibers between the capsules surrounding benign nodules (follicular adenoma) and malignant ones (Encapsulated-PTC) by using SHG microscopy images and FFT analysis of these images.

Our research indicates that different collagen structures can be detected in the malignant nodules capsule (PTC) compared to the benign nodule capsule and the thyroid capsule.

Higher orientation was detected for the malignant capsule but that does not mean the collagen fibers are organized or that the malignant tissue organizes the fibers. We believe it is rather a defense mechanism that goes from the level of the thyroid adjacent stroma of tumoral nodules.

Future plans

The present study deals with the differential diagnosis between follicular adenoma versus encapsulated – PTC, since both are clear cases, thus making it easier to prove the validity of the theory regarding the reorganizing of the collagen fibers within the two types of nodules, as proven with SHG Microscopy. Having completed that, the research may advance to analyzing less obvious situation:

1. Differential diagnostic between:
- Follicular adenoma versus follicular carcinoma;
- "Non-invasive follicular thyroid neoplasm with papillary-like nuclear features" (NIFTP) versus encapsulated papillary thyroid carcinoma with capsular invasion;
- Adenomatous nodule vs follicular adenoma.

2. Early detection of papillary carcinomas developed on follicular adenomas.

The SHG images can be developed as markers for use in clinical applications – a complementary method to early detection of suspected malignant nodules.

These above described microscopy methods help us distinguish between benign or malignant thyroid nodules, based on the capsular collagen organization.

ORIGINAL ARTICLE

Musculoskeletal sports injuries of the upper limb in children

Michail Kotsapas[1], Apostolos Gantsos[1], Symeon Naoum[2]

Abstract: *The participation of children and adolescents in sports is advantageous in many ways regarding their physical and mental health, promotes cooperation and socialization between them, prevents diseases, such as obesity, and also sets the base of a healthy lifestyle in adulthood. In addition, childhood per se is characterized by an increased level of physical activity. Nevertheless, despite the multiple benefits of physical activity, it does not lack the possibility of unfortunate events or harmful conditions. The inner need of the athlete for excellence and recognition, the effort to reach or keep on an elite level of sports, early sports specialization, and pressure derived from family and coaches often lead to sports injuries-diseases either acute or chronic. Many of these conditions sometimes are underestimated or undiagnosed in the Emergency Department, especially if the main complaining symptom does not correlate with the disease. This non-systematic literature review aimed to identify the most common upper limb sport related-injuries and conditions among pediatric athletes. These injuries are described into groups depending on the anatomical area e.g shoulder girdle, elbow joint, and wrist.*

Keywords: *sport-related injuries in children, sport-related injuries, pediatric athletes, musculoskeletal injury in sports, sports medicine, little league shoulder*

INTRODUCTION

Nowadays, children are encouraged to participate in sports at higher levels at a much younger age than before [1]. As a consequence, there are increasing numbers of young athletes visiting their pediatricians because of sports-related injuries or asking for a piece of advice regarding injury prevention [2]. However, children are not "small adults". Growth plates act as stress risers in the distal upper extremity, resulting in injuries that may have a serious impact on a child's overall growth, joint alignment, and/or extremity length [1]. Injuries of the ligaments in children usually present as avulsion injuries. Moreover, attention should be paid to comprehension of the soft tissue attachments of any bony spot seen in imaging studies.

From an economic standpoint, the economic burden of the above-mentioned injuries is quite considerable, especially among children and adolescents. Additionally, these injuries may have a long-term impact on the musculoskeletal system, resulting in decreased levels of physical activity [3].

This non-systematic literature review aimed to identify the most common upper limb sport related-injuries and conditions among pediatric athletes. The inclusion criteria for the selection of the articles were concerning pediatric athletes, musculoskeletal sport-related injuries, English language, published until October 2021 and access to the full text. The PubMed, Scopus and Google Scholar database were searched with the terms "musculoskeletal sport-related injuries in children", "youth" or "pediatric athletes", "musculoskeletal injury in sports". Both review articles and original research articles were used to synthesize this review with a focus on contemporary and seminal papers.

SHOULDER GIRDLE

Little League Shoulder

Most often seen in the dominant shoulder, this injury refers to an undisplaced type 1 Salter-Harris fracture (epiphysiolysis) of the proximal humerus and affects mostly young athletes involved in throwing sports (e.g. baseball pitchers) or in excessive overhead activity (e.g.

tennis)[1,2,4,5]. Young males are more commonly affected than females, while the peak prevalence of the disease presents at the time of the most rapid skeletal growth gain (11-16 years old for males) [4-6]. This injury is the result of the repetitive rotational and traction forces applied on the epiphysis, especially during the late cocking phase, with the humerus at maximum external rotation and abduction, and acceleration phase, where strong internal rotation and adduction forces are applied [7]. The increased overall number of throwing events is considered the most important risk factor for the prevalence of the disease. The patient's history may be remarkable for shoulder pain during sports that are alleviated at rest or correlated with an increase in practice intensity. Another complaint may be the deterioration of their athletic performance due to a decrease in throwing accuracy or velocity. On physical examination, glenohumeral internal rotation deficit (GIRD) may be noted. Radiographs are remarkable for physeal widening [5]. Sometimes, a radiographic evaluation of the contralateral shoulder is essential for the diagnosis [4]. At the late stages of the disease, premature fusion of the physis is noted, accompanied by angular deformity of the proximal humerus. Magnetic Resonance Imaging (MRI) of the shoulder is necessary for the diagnosis of the disease in patients with normal radiographs. In addition, MRI is useful for the evaluation of other soft tissue lesions, such as a rotator cuff (RC) tear, subacromial impingement, Superior Labrum Anterior to Posterior (SLAP) lesions, labral tears, etc [4,8]. The first line of treatment should be the cessation of throwing for at least 3 months. If symptom resolution is achieved, physical therapy is recommended with an emphasis on the strengthening of the shoulder girdle and posterior capsule stretching. Return to the sport should be gradual, and only after improvement of throwing technique through the appropriate practice sessions. Complications are rare thought serious, because of the developmental deformities of the physis that are included (premature physeal closure, growth arrest, upper limb length discrepancy, angular deformity, humeral head osteonecrosis) [4,5,8].

Glenohumeral Internal Rotation Deficit – GIRD

Young throwing athletes, such as baseball pitchers, even as young as 10 years old, are susceptible to this disease [9]. By definition, GIRD results in loss of internal rotation of the affected shoulder (more than 20°), compared to the contralateral shoulder [10]. Responsible for this range of motion (ROM) loss is considered the posterior capsular-rotator cuff tightness, which in turn causes abnormal shoulder deceleration during throwing [9,10]. At first, tightness results in a posterosuperior migration of the humeral head, as well as anterior capsule stretching, and, if left unaddressed, it leads to increased humeral head retroversion and abnormal shoulder functionality [5]. This condition predisposes young athletes to serious conditions, such as rotator cuff tears, internal impingement, labral tears, SLAP lesions, scapular dyskinesia, and Ulnar Collateral Ligament (UCL) injury of the ipsilateral elbow [5,9,10]. The patient's complaints include vague shoulder pain, stiffness, and the necessity for extended warmup or deterioration of their athletic performance. Physical examination should include meticulous shoulder ROM assessment and comparison with the contralateral limb in every thrower, who reports shoulder pain [6]. Furthermore, the physician should verify that the internal rotation ROM loss compensates with an equivalent external rotation ROM increase [4,10]. Plain radiographs rarely reveal abnormal findings, while MRI assessment of the soft tissue may reveal concomitant lesions. Management of GIRD requires rest from throwing activities for 6 months and physical therapy focused on posteroinferior capsular stretching, as well as, rotator cuff strengthening, and, fortunately, the prognosis is excellent for the majority of young patients [5][6]. Conservative treatment failure may require surgical management. Surgical management is, also, indicated, if concomitant lesions (e.g. rotator cuff tear) are present.

Rotator Cuff Disease

Rotator cuff tear is considered mainly an adult disease due to its rareness in underaged patients. Only 1.4% of children addressing a physician for shoulder pain are affected by rotator cuff tear [11]. Nevertheless, increased sports participation and early specialization in overhead activities result in a rising tendency of rotator cuff pathology at these ages [4,5,11,12]. Swimmers, baseball pitchers, throwers, tennis and volleyball players are particularly vulnerable to rotator cuff internal impingement, tendinitis, and, ultimately, tear because of the repetitive overhead and abduction-external rotation motion [5,11]. As far as swimmers are concerned, the term "swimmer's shoulder" is used to describe an overuse condition associated with impingement of the humeral head and the rotator cuff on the coracoacromial ligament [5]. It is difficult to make management recommendations on the rotator cuff tear in young patients because of the rarity of the disease. Even in the best available literature, information derives from case reports or small case series [11,12]. Each patient should be managed individually, and it is essential to take into consideration the level of the athlete, the necessity of a return to the pre-injury level, the injury as an entity (e.g. number of tendons affected, partial or full-thickness tears, concomitant soft tissue lesions, etc) [11]. Excellent functional outcomes in rotator cuff surgical repair are reported in limited case series studies although overhead athletes may not be able to play in the same position after surgery [11,12].

Shoulder Instability

Anterior shoulder dislocation is much more common (95%) than posterior dislocation or luxatio erecta [13,14]. About 1.7% of the general population is affected and 20% of the patients are younger than 20 years old, with a higher incidence in male patients [15]. Recurrence chance increases as the age of first dislocation decreases. The recurrence rate is as high as 90-95% for the age of the first dislocation under 25 years old [16], and in individuals with open physes escalates to almost 100% [13]. Nevertheless, some studies report significantly lower recurrence rates (33%) in ages of the first dislocation under 13, while for ages 14-17 recurrence exceeds 90% [17]. Risk factors for re-dislocation are age as abovementioned, male sex, contact sports, ligamentous laxity, and glenoid bone loss [4, 6, 13, 16, 17].

Patients with shoulder dislocation on examination present with asymmetry due to loss of the normal round shape of the shoulder, moderate to severe pain, and numbness, while the dislocated arm is usually supported by the healthy arm. The physical examination should always include the neurovascular assessment (especially the axillary nerve) of the affected arm. Plain radiographs are essential not only to confirm the diagnosis but also to exclude the fracture, before the reduction [6]. Many reduction manipulations have been described, such as the Hippocrates method, Kocher, or Stimson [16]. Some of them include the use of hard objects (e.g. the doctor’s heel in the Hippocrates method) to apply the necessary reduction force on the humeral head in the patient’s axilla [14]. Those techniques present an increased risk for neurovascular iatrogenic injuries due to the compression-traction of the axillary vessels, as well as the brachial plexus, and should be approached with caution [14]. The patient requires adequate analgesia and muscle relaxation medication, accompanied by psychological support, to achieve an effortless and painless reduction as soon as possible, with the fewest required manipulations. In case of failure to achieve a reduction in a conscious patient, general anesthesia might be necessary, especially in patients with heavy musculature. Reduction is usually felt by both the patient and the physician, by palpation, hearing, and, also, visually as the shoulder regains its normal round shape. Post-reduction neurovascular assessment should be performed, and a plain radiograph is necessary to confirm reduction and exclude any manipulation-related fracture [14]. After the reduction, a shoulder sling is used [6,16]. Position of immobilization in external rotation and adduction, despite support by many authors in the past, seems to have similar results in soft tissue healing and recurrence rate compared to immobilization in internal rotation and adduction [13,16]. The duration of immobilization is, also, a matter of debate [13,16].

Existing literature supports surgical stabilization after the first episode of shoulder dislocation, as far as active young adults are concerned. On the other hand, such a literature unanimity does not exist, regarding underaged active patients, who experience their first dislocation episode. According to Franklin et al. [15], conservative management of underaged patients leads to a higher recurrence rate (approximately 70-73). In addition, return to play rates are significantly higher for the athletes who underwent surgery (95.3% operative vs 41,3% nonoperative, Zaremski et al.) [18]. In conclusion, young active underaged patients are more prone to re-dislocation, so the benefits and drawbacks of both operative and nonoperative management should be thoroughly presented and discussed with the patient and the parents, to choose the best available method of treatment [15].

ELBOW

Ulnar Collateral Ligament Injury

Growth plate injuries are much more common in skeletally immature patients than injuries of the attached ligaments [4,5,19]. However, due to single-sport specialization and the intensity of throwing programs at an early age, ulnar collateral ligament (UCL) injury rates seem to rise among pediatric and adolescent overhead athletes population [20,21]. In pediatric patients, injuries to the anterior bundle of UCL are more common than in the posterior bundle [21] and might refer to partial or full tears, attenuation, or insufficiency of the ligament [5,22]. In cases of acute injuries, the patient usually experiences a popping sensation associated with swelling, ecchymosis, and pain on the medial or posterior elbow aggravated during late cocking and acceleration phases of throwing [5,13,22]. The valgus stress test of the elbow may indicate instability [22]. Patients with chronic injuries complain of vague medial elbow pain and deterioration of their throwing performance [22]. Plain radiographs are necessary to exclude pathologic findings, such as fractures-epiphysiolyses or avulsion of the medial epicondyle. MRI is indicated in the evaluation of the UCL in the case of normal radiographs. Initial treatment consists of cessation of throwing, ice therapy bracing and analgesics, followed by physical therapy and gradual return to sports [5,21]. In elite adult athletes, in case of conservative treatment failure, UCL reconstruction is preferred over UCL repair. Nevertheless, optimal surgical management is less clear regarding adolescent patients even if athletes between 15-19 years represent the largest patient population, in which UCL reconstruction is performed [22]. The newest available data present an 80% and 84% rate of return to play at the same or higher level of competition for javelin throwers and baseball players respectively, following UCL reconstruction [20].

Little League Elbow

Little League Elbow is an umbrella term used to describe medial elbow painful pathologic conditions that affect skeletally immature overhead athletes, such as medial epicondyle apophysitis, avulsions or stress fractures, UCL injuries, and flexor-pronator mass strains [4-6,8, 19, 23]. Tension overload of the medial elbow, as a result of the repetitive valgus stress experienced by these athletes during throwing, is the responsible mechanism [19]. Pitching despite the symptoms, high-speed fastballs, throwing breaking pitches, increased pitches per game, and year-round play are considered risk factors for the prevalence of the disease [19]. Apart from medial elbow pain, the young throwers complain of deterioration of their throwing accuracy or velocity. On plain radiographs, the medial epicondyle may be displaced. In case of doubt, an examination of the contralateral elbow may be required [6]. Management of flexor-pronator muscle strains and apophysitis of the medial epicondyle is conservative and includes cessation of throwing and physical therapy [19]. Avulsion fractures with a displacement of less than 5mm should be initially immobilized and follow an early range of motion physical therapy protocol. Displacement of more than 5mm may require open reduction and internal fixation of the affected medial epicondyle [5,6,19].

Osteochondritis dissecans (OCD)

Repetitive microtrauma, associated with axial compression forces or valgus stress, is considered to be the main etiologic factor for the development of the disease. This notion is amplified by the fact that OCD is more common in skeletally immature throwers and gymnasts. The elbows of skeletally mature athletes are rarely involved, probably due to the greater blood supply of the mature distal humeral epiphysis. The capitellum of the dominant upper limb is affected more often and males are more prone to elbow OCD than females [5,23-25]. Patients usually complain of lateral elbow pain and, as the disease progresses, mechanical symptoms may present, such as locking, clicking, decreased ROM, and swelling [25,26]. Early diagnosis is essential to avoid chondral fragmentation and loose body formation, which may lead to degenerative lesions at a young age [26]. Late-stage OCD may appear as increased radiolucency of the capitellum or loose intraarticular bodies on plain radiographs [19,25]. In the case of radiographs with normal findings and strong suspicion of OCD, an elbow MRI should be obtained, which provides the optimal evaluation of the lesion stability [27, 28]. In general, the stability of the lesion indicates roughly the conservative or surgical management of the disease [28]. Most of the early-stage lesions in patients with open physes are best managed nonoperatively [5,25,28]. Unstable symptomatic lesions (pain, decreased ROM, locking, fragmentation, closed physes) require surgical intervention. Although a consensus does not exist due to insufficient reliable data and many treatment modalities have been reported (arthroscopic debridement, abrasion chondroplasty, microfractures, fragment fixation, osteochondral autograft transplantation-OAT, costal osteochondral transplantation-CAT), it seems that osteochondral autografting techniques may be superior in restoring the local anatomy and elbow function.

OCD of the elbow should not be confused with Panner's disease, which is a self-limiting osteochondrosis of the capitellum, with an excellent prognosis. It affects more commonly children of younger age (4-9 years old). On physical examination, symptoms may be mimicking those of the OCD. Conservative management (cessation of activities, analgesics, and immobilization) is sufficient [19].

Olecranon apophysitis

Similar to the Osgood-Schlatter (tibial tubercle apophysitis) disease, olecranon apophysitis is the result of traction microtrauma due to the repetitive contraction of the extension mechanism, in skeletally immature athletes. Apophysitis may progress to avulsion fractures in younger patients or stress fractures in older individuals. Posterior elbow tenderness, swelling, and decreased ROM are the most common complaints. Conservative management with rest, activity modification, and analgesics is often the treatment of choice [5,19,29]. In the case of olecranon apophyseal nonunion surgical management may provide satisfactory results [30].

WRIST

Distal Radius Fractures

These fractures are the most common children's fractures (20% of all fractures), with a predominance in male patients, and happen usually in contact sports, such as soccer [1, 5,31]. A developing skeleton is characterized by unique fracture patterns, such as buckle fractures, greenstick fractures, plastic deformation, and epiphysiolysis [1,31]. Children's fractures, also, present a great healing and remodeling potential. Remodeling is more eminent near the most active physes, in the plane of joint motion, and younger skeletal age [31]. The pediatric trauma surgeon should consider the abovementioned, as well as the patient's and parents' capability of compliance, before applying the proper treatment. Surgical intervention must be performed with minimal physeal trauma. Growth arrest is a devastating complication of physeal injuries, affecting up to 10% of physeal fractures and may cause deformities, such as length discrepancy, angulation, and joint incongruency, ultimately leading to lifelong disability [1,31].

Gymnast's Wrist

The distal radial physis of the young gymnast not only does suffer from fractures or epiphysiolyses, but also chronic overuse injuries, such as the "gymnast's wrist" [4,5]. Due to the needs of this particular sport, the wrist of the pediatric athlete is forced to bear heavy axial loads with the wrist in full extension multiple times during practice or competition [1,23]. The repetition of this abnormal loading pattern is responsible for microtrauma to the physis, which may even lead to physeal arrest [1,5]. Plain wrist radiographs in young gymnasts with wrist pain and contralateral comparison, regardless of the physical examination signs, are suggested by some authors [1]. Abstaining from gymnastics may be a necessity if any abnormality, such as irregularity or physeal widening, is noticed on radiographs. A cast may also be applied [1,5]. In the case of normal x-rays, an MRI may reveal bone marrow edema on both the proximal and distal side of the physis [4]. Management of patients with physeal arrest might be quite challenging and depends on the years remaining until expected physeal closure, the portion of physis with physeal arrest, and the existence of deformity (ulnar positive variance, bowing), and the articular congruency. Surgical treatment options include recurrent radial lengthening, both radial, and ulnar lengthening, radial osteotomies, and ulnar epiphysiodesis. Despite the good results reported, most of the patients will not be able to return to their previous level of gymnastics [1].

Myocardial work – are we ready for a new parameter in clinical practice for evaluating left ventricle function?

Maria M. Gurzun[1,2], Diana Iancu[1], Mădălina Badea[1], Mihaela Anton[1], Silviu M. Stanciu[1,2]

Abstract: *Left ventricle systolic function is an essential parameter in different clinical scenarios and the usual methods available for its assessment are sometime suboptimal, depending on the filling conditions of the heart. Therefore, the development and implementation in clinical practice of a new parameter for assessing left ventricle contractile function is desirable. Mechanical work defined as energy transferred to or from an object via the application of force along a displacement seems to be a promising method for myocardial performance estimation. Although initially this parameter was calculated on the left ventricle volume-pressure curve estimated by cardiac catheterization, an easier method considering non-invasive left ventricle pressure and global longitudinal strain assessed by speckle tracking echocardiography was developed recently. Myocardial work offers information regarding the segmental and global function of the left ventricle, and it is considered a more sensitive marker for assessing left ventricle performance compared to ejection fraction and global longitudinal strain. Its applicability in various cardiac pathologies was demonstrated recently in several studies and its use in every day practice may bring important additional information for clinical decision making.*

Keywords: *myocardial work, mechanical work, global work, systolic function*

INTRODUCTION

Left ventricle systolic function is an essential parameter in different clinical scenarios and its accurate estimation is mandatory in every day clinical practice. The methods available for assessing left ventricular (LV) contractile function, such as ejection fraction (LVEF) or global longitudinal strain (GLS) are dependent on the filling conditions of the heart. Myocardial work (MW) emerged as a promising option for assessing LV systolic performance, as a more reliable and independent technique. This method removes afterload dependence by incorporating it into the analysis of the GLS [1,2,3].

Mechanical work is defined as energy transferred to or from an object via the application of force along a displacement. This formula is not well suited for the heart because it is difficult to calculate the myocardial force applied during the cardiac cycle. Therefore, the idea of using pressure as a substitute for force arose. This is defined as the force applied to the LV walls divided into several segments. Usually, myocardial work is determined based on the volume-pressure curve in the LV, obtained by cardiac catheterization. This method was introduced in 1979 by Saga and reflects myocardial oxygen consumption and LV contractile function. However, the clinical utility is reduced as it requires an invasive maneuver [1,2,3].

An easier method of approximating mechanical work takes into consideration non-invasive LV pressure and GLS, a concept developed by Russel and colleagues. The LV pressure curve is estimated by incorporating the systolic blood pressure measured at the brachial level and the phases of the cardiac cycle (isovolumic relaxation phase, ejection phase, isovolumic contraction phase), established using echocardiography. In their study, the LV volume-pressure curve correlates with the pressure-strain curve in patients with left bundle branch block and intra-ventricular contraction asynchrony or in those with ischemic heart disease. Therefore, myocardial work is a promising method

for non-invasive exploration of LV myocardial performance, already validated for several clinical situations [1,2,3].

ACQUISITION AND ANALYSIS

Myocardial work is obtained by using a speckle-tracking technique. The necessary ultrasound acquisitions include the apical four, two and three chamber views, to generate the global longitudinal strain. It is necessary to acquire images at 60-80 frames/second, to properly visualize the edge of the endocardium and to establish an adequate width of the region of interest at the level of the myocardium, to allow the correct evaluation of GLS and, thus, of myocardial work [1,2].

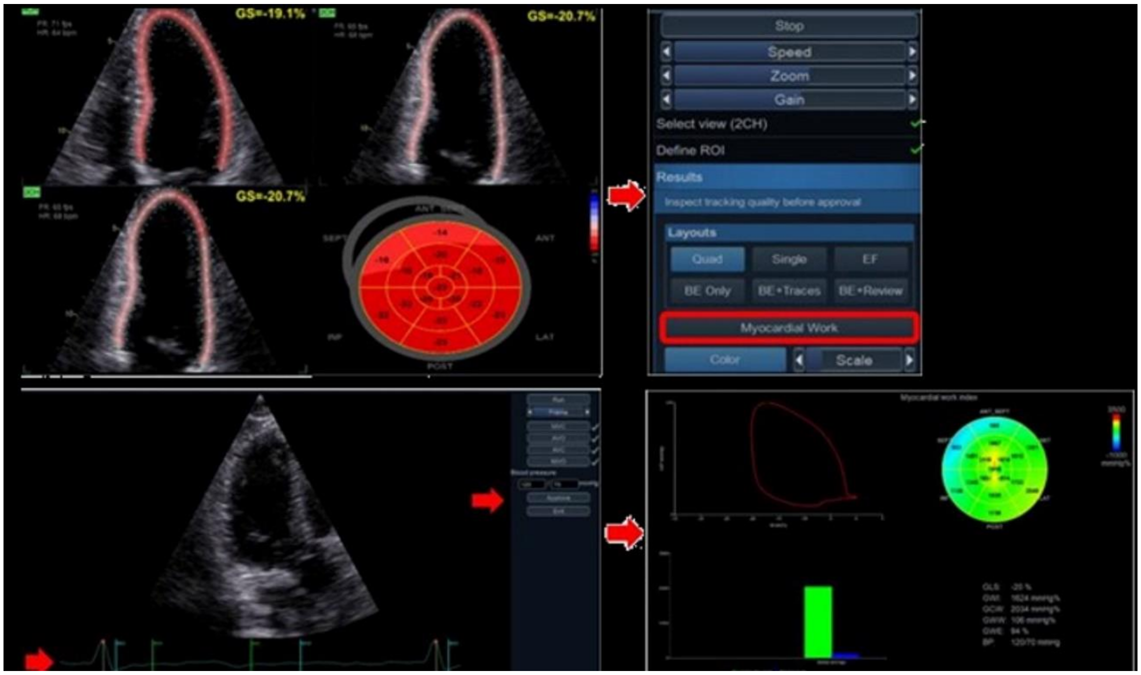
Blood pressure measurement using a standard cuff placed at the brachial level should be performed simultaneously with the acquisition of echocardiographic images. This is an essential parameter used as a surrogate for LV systolic pressure for the calculation of the global work index [2].

After obtaining the GLS and the characteristic bull's eye image, the opening and closing of the aortic and mitral valves will be selected in an automatic or manual manner, guided by the three-chamber apical view and the concomitant electrocardiogram. The LV volume-pressure curve is generated from an empirical curve, modified according to the duration of the isovolumic contraction phase and the ejection phase. These phases are determined by echocardiography after selecting the moments attributed to the opening and closing of the aortic and mitral valves. Thus, it is possible to define the phases of the cardiac cycle. The maximum LV systolic pressure is equal to the systolic blood pressure, in the absence of a gradient in the LV ejection tract or at the aortic valve [1].

Subsequently, systolic, and diastolic blood pressure are introduced into the formula and the calculation of myocardial work is approved (Figure 1) [2].

Myocardial work is measured by the area of the LV pressure-strain curve, generated based on filling pressures and GLS1. Myocardial work is composed of several parameters - global work index, global constructed work, global wasted work, and global work efficiency [1].

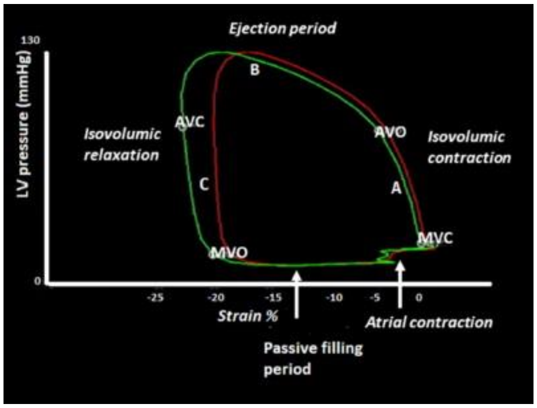
Figure 1: The first step in the MW method involves acquiring four-, two-, and three-chamber apical views, followed by GLS calculation. The myocardial work option is then selected, followed by the introduction of blood pressure values (systolic, diastolic) and the selection of the opening and closing moments of the aortic and mitral valves, guided by the concomitant electrocardiogram. Based on the pressure-strain curve, myocardial work is calculated, along with its components, the bull's eye image is generated for the myocardial work index (with the values of this parameter on a 17 segments model, along with the color code) and the relationship between constructed work and wasted work through the bar chart.



GLS: -20 %
GWI: 1624 mmHg%
GCW: 2034 mmHg%
GWW: 106 mmHg%
GWE: 94 %
BP: 120/70 mmHg

Global work index is calculated by the area of the pressure-strain curve resulting from the closing and opening of the mitral valve (Figure 2), representing the mechanical systole, including the phase of contraction and isovolumic relaxation. Given that pressure is used instead of force, it is not possible to calculate myocardial work, but an index of it (GWI) [2].

Figure 2: The pressure-strain curve, along with the phases of the cardiac cycle and the moments of closure and opening of the aortic and mitral valves. Adapted from (1). AVC - aortic valve closure, AVO - aortic valve opening, MVC - mitral valve closure, MVO - mitral valve opening.



Normally, the myocardial segments contract and relax synchronously to participate constructively in achieving the stroke volume.

Global constructed work (GCW) represents the productive work submitted by the LV for achieving systolic shortening and elongation during the period of isovolumic relaxation, the physiological processes carried out between the opening of the aortic valve and the mitral valve [1,3].

Consumed work (global wasted work) represents the unproductive effort made to elongate the myocardial fibers in the LV systole and shorten them in the isovolumic relaxation phase. It occurs in cases with asynchronous intraventricular contraction, such as patients with bundle branch block or myocardial ischemia.

Global wasted work (GWW) increases the metabolic burden of LV and may contribute to its remodeling [1,2,3].

Global work efficiency (GWE) is the constructed work divided by the sum of the constructed and consumed work. This parameter expresses how efficiently energy was invested during the cardiac cycle and is reported as a percentage.

Therefore, the value for a normal heart with synchronous contraction and relaxation, this value should be close to 100% [1]. This parameter is reported in the form of a bull's eye numerically and by color code (green indicates areas with a high degree of efficiency and red indicates areas with a low degree of efficiency). Possible clinical applications for determining this parameter include improved selection criteria for cardiac resynchronization therapy (CRT) or for revascularization of patients with myocardial infarction [1,2,3].

The parameters described above are evaluated globally and segmentally (17 segments), generating a bull's eye, like GLS. The global work index can be evaluated visually by means of a color scale - red represents an intense work area, green normal work, and blue negative work. In the case of negative work, energy consumption exceeds production, due to elongation of fibers during systole or shortening during the period of isovolumic relaxation.

NORMAL REFERENCE VALUES

The NORRE study conducted by the European Association for Cardiovascular Imaging was the first prospective, multi-center study to include a large group of 226 healthy volunteers between the ages of 20 and 78, to establish reference values for myocardial work and its parameters [1,2]. The values obtained in this study are presented in Table 1.

Other studies on healthy volunteers resulted from the STAAB cohort or the study led by Galli5, with the results shown in Table 2.

The results obtained in the two studies were similar, indicating normal values above 95% for GWE. GWW has low values in healthy subjects, but not equal to zero.

Table 1: Reference values for myocardial work parameters according to the NORRE study. Adapted from [2].

	Total number (n=226)	**Male (n=85)**	**Female (n=141)**
GWI (mm Hg%)	1,896 ±308	1,849 ± 295	1,924 ±313
GCW (mm Hg%)	2,232 ± 331	2,228 ± 295	2,234 ±352
GWW (mm Hg%)	78,5 (53-122,2)	94 (61,5-130,5)	74 (49,5-111)
GWE (%)	96 (94-97)	95 (94-97)	96 (94-97)

Table 2: Normal reference values of myocardial work from three studies with healthy subjects. Adapted from [1].

Variabile	GWI	GCW	GWW	GWE
NORRE study	1,896 ±308	2,232 ±331	78,5 (53-122,2)	96 (94-97)
STAAB cohort	2,209 ±307	2,430 ±351	74 (54-101)	96 (95-97)
Galli et al.	1,926 ±247	2,224 ±229	90 (62-123)	96 (94-97)

An example of myocardial work for a healthy subject is shown in Figure 3A**.**

PRACTICAL APPLICATIONS OF MYOCARDIAL WORK

MW is considered a more sensitive marker for assessing LV performance compared to ejection fraction and GLS. Its applicability in various cardiac pathologies was demonstrated in several studies [4].

Bundle branch block

In a normally functioning heart, all 17 segments contract at the same time and contribute to the ejection of the blood into the aorta, resulting in a very low GWW value. In the presence of a bundle branch block, certain LV segments elongate in the systole or contract against a closed aortic valve, resulting in a significant increase in GWW. GWW does not contribute to LV ejection, which explains why MW is more sensitive in assessing LV efficiency, even when LV contractility is normal [4].

Cardiac resynchronization therapy (CRT)

Galli et al demonstrated a potential role of MW in assessing post-CRT response [5]. Thus, at baseline, GCW and GWW were significantly higher in CRT responders compared to non-responders. Following a multivariate analysis, values of GCW > 1057 mmHg % and GWW > 384 mmHg % were considered predictive of positive response post-CRT.

The 6-month reassessment after the intervention showed that responders had an increase in GCW and a decrease in GWW associated with reverse LV remodeling.

Figure 3: A – Normal heart - GWI and GWE within normal limits with GCW predominance over GWW, GLS with normal value; B – Arterial hypertension - GLS is normal, while MW bull's eye shows elevated values of GWI and GCW, with a normal value of GWE

Van der Bijl et al also evaluated patients with resynchronization indication, concluding that another predictor for CRT response is GWE, with lower values before CRT being associated with a better prognosis [6].

In another study, Galli et al analyzed the effect of a preserved GCW value regarding echocardiographic response and post-CRT mortality, showing that GCW > 888 mmHg% correlated with a 15% reduction in LV telesystolic volume and a significant decrease of mortality compared to lower values [7].

Arterial hypertension

Loncaric et al have shown that under acute pressure overload, the LV ejection fraction remains unchanged, while the GLS decreases and the MW increases.4 In these patients, the MW increases, as each myocardial segment must produce additional energy to pump blood against an increased afterload.

Under conditions which involve chronic exposure to pressure overload, LV remodeling occurs, with myocardial hypertrophy and fibrosis, and in this situation the MW values decrease (Figure 3B).

Chronic heart failure (HF)

a) *with preserved LV ejection fraction*

Chronic heart failure with preserved LVEF is becoming an increasingly diagnosed entity, the main pathophysiological mechanism being the presence of diastolic dysfunction. Paolisso et al followed the role of MW in predicting the first hospitalization caused by HF in patients with preserved LVEF, showing that an increased value of GWW with a cut-off of 170 mmHg % was associated with a higher percentage of patients being hospitalized [8].

b) *with decreased LV ejection fraction*

Hedwig et al demonstrated a good correlation between GWI and traditional echocardiographic parameters (LVEF, GLS), but also with the NT-proBNP value and the maximum O_2 consumption in the cardiopulmonary exercise test, a GWI value < 500 mmHg % having a negative predictive role [9]. An example is presented in Figure 4A.

Figure 4: A – Nonischemic dilated cardiomyopathy - severely reduced GWI and GCW and high GWW; B – Hypertrophic cardiomyopathy - low GWI and GCW and high GWW, noting a scratchy pattern of MW distribution due to the presence of asymmetric hypertrophy, especially in the lateral LV wall and in the mid and apical segments; C – Coronary heart disease - the red curve shows the overall value of MWI, while the green curve shows the pressure-volume curve at the level of a normal myocardial segment (C1) compared to an akinetic segment (C2). There is a lower value of GCW and a higher value of GWW in the akinetic segment compared to the normokinetic segment.

Wang et al showed that patients with a GWI < 750 mmHg % had a significantly higher risk of mortality and a higher rate of hospitalization due to HF compared with those who had a GWI > 750 mmHg % [10].

In another study by Bouali et al, in patients treated with sacubitril/valsartan there was an improvement in both conventional echocardiographic parameters and GCW and MWE at reevaluation, 12 months after initiation of treatment. Instead, the GWW remained unchanged. A GCW value ≤ 910 mmHg at baseline was associated with more advanced disease, higher LV telediastolic volume, and lower LVEF, and was also a predictor of major cardiac adverse events [11].

Coronary heart disease

Evaluation of patients with coronary heart disease is difficult in the absence of LV regional dysfunction. Echocardiographic evaluation is based on subjective methods, to establish the segmental and global systolic LV function. MW has shown better sensitivity and accuracy compared to LVEF and GLS in identifying patients with coronary heart disease. Edwards et al demonstrated that GWI is a strong predictor. A GWI cut-off value of 1810 mmHg % had a specificity of 92% and a sensitivity of 51% [12]. An example is presented in Figures 4C1 and C2.

Boe et al analyzed a cohort of patients with acute coronary syndrome without ST-segment elevation, showing that GWI is significantly lower in the territory supplied by the coronary artery at risk of acute occlusion, being an important parameter that could guide the indication for prompt intervention [13]. Meimoun et al studied MW in patients with anterior ST-segment elevation myocardial infarction, showing that GCW is the best parameter to predict segmental and global LV recovery [14].

The use of MW was also attempted in the echocardiographic stress test, with Borrie et al demonstrating a significant decrease in GWI among LV segments with inducible ischemia, in contrast to healthy subjects in which a 54% increase in GWI was obtained [15].

Hypertrophic cardiomyopathy

There is several studies that have observed the evolution of MW in patients with hypertrophic cardiomyopathy (HCM). Hiemstra et al showed that GCW, GWI and GWE were significantly reduced, while the value of GWW was increased among patients with HCM [16]. An example is presented in Figure 4B.

GCW was the only predictor for the presence of myocardial fibrosis confirmed by cardiac magnetic resonance, with values < 1623 mmHg% proving a good sensitivity and specificity (82% and respectively 67%) [17].

Figure 5: A – Aortic stenosis- The average aortic transvalvular gradient was added to systolic blood pressure to estimate LV afterload. We can observe that, although the GLS value is similar for two patients with aortic stenosis, the first patient has lower values of GWI and GCW (A1) compared to the second one (A2), the first one having more severe symptoms; B – Mitral regurgitation - normal values of GCW and GWI are observed in a patient with severe asymptomatic mitral regurgitation; C – Aortic regurgitation - normal values of the parameters in a patient with asymptomatic chronic severe aortic regurgitation

In patients with asymmetric LV wall hypertrophy, a scratchy pattern of MW distribution was observed. In this case, segmental MW values were more useful in predicting the presence of myocardial fibrosis compared to global ones [18].

Different segmental values were also identified among patients with other HCM phenocopies. Clemmensen et al also showed that in patients with cardiac amyloidosis the MW values were significantly lower compared to healthy subjects. At the same time, lower values of GWI were observed in the basal segments compared to the apical ones, and GWI was associated with a lower effort capacity and a worse prognosis [19].

Valvular heart disease

a) *Aortic stenosis*

To estimate more accurately LV afterload, Jain et al added the mean aortic gradient to systolic blood pressure, demonstrating a good correlation with invasive measurements of systolic blood pressure. In the same study, the authors demonstrated an immediate decrease of MW in post-TAVR patients [20].

Another study found that in patients with aortic stenosis, the presence of more severe symptoms of heart failure correlated with lower values of GWI and GCW, consistent with the presence of a higher degree of myocardial fibrosis secondary to chronic exposure to increased afterload [21].

A practical example is shown in Figure 5 A1 and A2.

b) *Aortic regurgitation*

Evaluation of MW in patients with chronic severe aortic regurgitation and preserved LVEF could provide additional information on myocardial performance. Meucci et al recently published a study showing that patients with severe aortic regurgitation and preserved LVEF have elevated or normal GWI and GCW values and normal GWE and GWW values [22]. An example is shown in Figure 5C.

c) *Mitral regurgitation*

Tunyan et al analyzed MW in patients with primary mitral regurgitation. LVEF, GLS, and GWI did not differ between symptomatic and asymptomatic patients, but symptomatic patients had lower GCW and higher GWW values [23]. An example is shown in Figure 5B.

MW was also evaluated in patients with HF with reduced LVEF and severe functional mitral regurgitation in whom Mitra-Clip was performed. The study showed that GCW was the only predictor for LV reverse-remodeling one year after surgery, a GCW value > 846 mmHg % being associated with a decrease of > 10% in the LV telesystolic volume [1].

CONCLUSIONS

MW is a new method, less dependent on the LV loading conditions compared to LVEF and GLS, which provides important information about the segmental and global function of the LV. In recent years, promising results have been obtained on the applicability of MW in various cardiac pathologies, vouching the significant additional role MW could play in daily practice.

Negative-pressure wound therapy - advantages and disadvantages

George Pariza[1,2], Carmen I. Mavrodin[1,2], Valentina A. Buzatu[1,2], Natalia Turcan[2], Monica M. Cirstoiu[3,4], Bogdan Cretu[5,6], Catalin Cirstoiu[5,6]

Abstract: *The applications of negative-pressure wound therapy (NPWT) have achieved remarkable diversification. Initially used in the therapy of soft tissue wounds related to open fractures, this technique led to the understanding of the complex mechanisms underlying it. This paper aims to analyze the evolutionary scenarios of a group of patients with heterogeneous lesions under negative pressure aspiration treatment. We aimed to identify and analyze various associated pathologies that have the potential to negatively influence the healing process under negative pressure treatment and implicitly analyze the particularities of representative cases for the group whose evolution under treatment proved to be unfavorable. Retrospective, observational study, type series of cases focused on a group of 17 hospitalized patients, who received treatment by negative aspiration, between 2015-2019 in the Surgery Department of the University Emergency Hospital Bucharest. Regarding the obtained results, diabetes mellitus, obliterating arteriopathy, and anemia had a prevalent distribution in the group with unfavorable evolution. The glycemic value can predict 17% of the evolutionary scenario of a patient (favorable/unfavorable) being necessary an integrative therapeutic conduct. Concluding, although an extremely promising therapeutic option, NPWT can prove to be disappointing given its impact in the background of suboptimally managed comorbidities.*

Keywords: *negative pressure therapy, negative prognosis, comorbidities, amputation, wound complications, lower limb obliterative arteriopathy*

INTRODUCTION

The negative-pressure wound therapy (NPWT) method involves the application of a negative (subatmospheric) pressure to the wounds in a controlled manner [1]. Using a system consisting of a vacuum source, a porous material (filler) arranged inside the wound that respects its limits, a polyurethane adhesive film, which is transparent, permeable to water vapor, and impermeable to bacteria, this therapy method ensures tightness [2]. The first indications of negative pressure aspiration therapy cited in the literature were in the management of soft tissue lesions associated with open fractures and for closing dermatofasciotomy wounds [3]. Currently, after numerous studies have elucidated many complex gears underlying the mechanism of action and it was possible to understand how the overall therapeutic effect is influenced by these mechanisms, the range of therapeutic indications has gained remarkable proportion [4].

There are many ways in which negative wound pressure suction therapy promotes healing [5]. The suction force acting on the lesion drains the exudate and causes mechanical stress at the edges of the wound [6]. This mechanical stress alters the local tissue perfusion, consequently stimulating angiogenesis and the development of granulation tissue [7].

The changes in tissue perfusion induced by NPWT are a consequence of multiple determinism. Angiogenesis is responsible for a part of the perfusion changes [8]. In addition, pressure modifications from the wound and the physical changes of the existing blood vessels, which in turn initiate alterations in blood rheology, are other important components of the angiogenesis process [9]. Various studies have concluded that these perfusion changes induced by NPWT depend on several factors [10]. The first factor is the regime of application of negative pressure (continuous or intermittent) [11]. Then, the pressure regime used (-50mmHg - -200mmHg), the condition of the tissue (healthy/ ischemic), the type of tissue, as well as its proximity to the area on which the negative pressure acts [12].

The healing process can be influenced by modifying various functional and material parameters [13]. Thus, the pressure level, the application of the pressure regime (continuous/ intermittent), the type of filler material (foam/gauze), the presence of additional layers in contact with the wound, installation, etc., represent the therapeutic variables that must be agreed with the patient’s particularities. Respectively, the patient’s pathology, the type of wound, even its shape are factors to consider [14]. All these data play a key role in the therapeutic equation, whose ultimate goal is to obtain the maximum therapeutic benefit and minimize the disadvantages as much as possible [15].

Numerous studies on different types of wounds have revealed that NPWT is a more economical treatment method compared to conventional ones [16]. This involves the use of fewer dressings, and the frequency with which other reconstructive options are used is lower [17]. The healing time of wounds is shorter, and the overall duration of treatment and hospitalization is remarkably reduced [18]. Although the materials used in NPWT are at the beginning more expensive than those required for conventional treatment, in the long run, the costs of conventional therapy outweigh those of NPWT [19].

NPWT was introduced as a preventing technique for post-cesarean delivery wound morbidity, especially for obese women. The reported results are controversial; the heterogeneity of the results being summarized in two suggestive meta-analyses [20]. The background for using preventive NPWT consists in the actual rising trend of obesity and cesarean delivery among pregnant women and the compelling data regarding the results of this therapy in non-obstetrical surgical specialties [21]. However, at this moment, there are no valid studies to demonstrate that the use of NPWT is beneficial as a prevention strategy for wound infections and complications in the obstetric population; it is also not justified in the matter of economical features [22].

MATERIALS AND METHODS

The retrospective study used data collected from the computer database of the hospital, respectively the discharge summaries of the patients. The data collection process focused on the following: demographic data, hospitalization duration, and the main diagnosis. Special attention was given to the associated pathologies that may influence the evolution of lesions of interest under treatment with negative pressure (lower limb obliterative arteriopathy – LLOA, anemia, atherosclerosis, type II diabetes). In addition, other factors were registered, such as laboratory tests (complete blood count, biochemistry analyses, laboratory tests for hemostasis), general clinical examination data, paraclinical investigations (radiography, Doppler ultrasound, angiography, CT (computed tomography), angio-CT), the nature of the primary and subsequent intervention, clinical evolution on the period of hospitalization under negative pressure therapy, the post-vacuum aspect of the lesions, the clinical condition of the patient and the aspect of the lesions of interest at the post-discharge controls.

The centralized data were analyzed descriptively using Microsoft Excel 2019. SPSS Statistics software was used to perform logistic regressions. After the first session of NPWT, the division of patients into the two groups reflecting the general evolution (favorable/unfavorable) and the post-vacuum aspect of the lesions of interest was considered.

Objectives

We aimed to analyze the prognosis of a group of patients with heterogeneous lesions undergoing NPWT. Our objectives included the identification and division of cases according to the favorable/unfavorable evolution of lesions of interest. It also included the appreciation of the distribution among patients of various associated comorbidities significant for the targeted population; according to literature, they have the potential to negatively impact the healing process, even under NPWT (diabetes, obliterating arteriopathy, anemia). We also looked into the analysis of the particularities of the representative cases from the study group whose evolution under treatment proved to be unfavorable.

RESULTS

According to the inclusion criteria, a group of 17 patients was identified (5 female patients and 12 male patients), aged between 47 and 80 years, the average age being 62 years between 01.01.2015 - 31.12.2019, within the General Surgery III Department of the University Emergency Hospital of Bucharest. The situation of inpatient diagnoses, as well as the prognosis balance, are presented in a more schematic framework in Table 1.

Table 1: Inpatient diagnoses of the studied group

Diagnosis at admission	Patients no.	Prognosis
Gangrene in the lower limbs with various locations	7	Favorable – 5 Unfavorable – 2
Foot trophic ulcer	2	Unfavorable
Secondary purulent peritonitis	2	Unfavorable
Local complications of postoperative wound	5	Favorable – 4 Unfavorable – 1
Necrotizing fasciitis and cellulite of the abdominal wall	1	Favorable

Regarding the prognosis scenarios under NPWT, 7 patients (2 women and 5 men) showed an unfavorable course, the remaining 10 patients (3 women and 7 men) presenting an improved aspect of the lesions of post-vacuum interest (Table 2) (Figure 1).

Following the centralization of the number of hospitalization days, it was possible to outline a distribution of patients, respectively, the minimum number of hospitalization days (six), as well as the maximum number of days of hospitalization (seventy-five). Intuitively, the minimum duration of hospitalization was recorded in the favorable outcome group. Somewhat more edifying, it turned out to be the average number of days of hospitalization, calculated for each group. Therefore, an average of 22 days of hospitalization corresponded to the group with a favorable outcome, while for the group with an unfavorable prognosis, the average number of days of hospitalization was 40 days, with an increase of approximately 45% of the average time spent in the hospital and all its related costs.

Regarding the associated pathologies studied, respectively type II diabetes, anemia and LLOA, were identified in both groups, but overall there was a greater aggregation of these comorbidities within the group with an unfavorable prognosis.

Figure 1: A. Myxofibrosarcoma of the thigh; B. Wound dehiscence after hip disarticulation; C. Wound dehiscence treated with NPWT; D. improved lesion post vacuum therapy

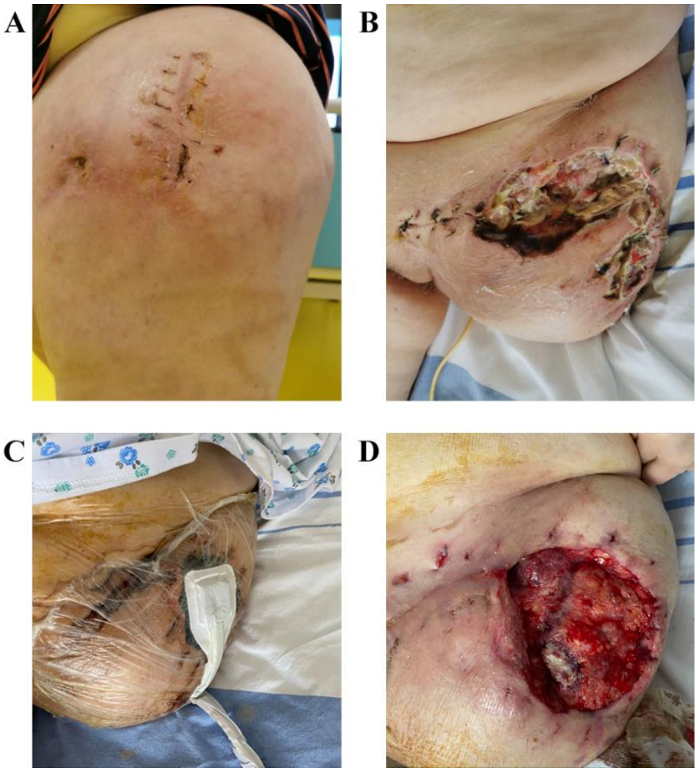

Table 2: The detailed situation of the study group situation regarding the evolution of the diagnosis and the number of hospitalization days.

Diagnosis at admission	Post NPWT	Hospitalization days
Post-operatory wound suppuration	Improved	6
Leg gangrene	Improved	11
Gangrene at the level of the stump after amputation of the toe	Gangrene at the level of the stump	11
Forefoot gangrene	Improved	12
Post-operatory wound seroma	Improved	15
Stump gangrene after amputation of fingers II-V	Improved	15
Post-operatory wound suppuration	Improved	19
Secondary purulent peritonitis (strangulated eventration)	Wound seroma	24
Finger V gangrene	Improved	25
Calf gangrene	Improved	27
Post-operatory wound suppuration	Wound suppuration	31
Necrotizing fasciitis, abdominal wall cellulite	Improved	36
Heel trophic ulcer	Trophic ulcer	40
Leg gangrene	Gangrene at the level of the stump	52
Secondary purulent peritonitis (perforated gastric ulcer)	Wound dehiscence	53
Post-operatory skin necrosis	Improved	56
Toe trophic ulcer	Gangrene at the level of the stump	75

The particularities of the distribution of comorbidities in the studied group of patients are as follows:

- 5 patients diagnosed with LLOA; 4 belong to the group with unfavorable evolution;
- 9 patients diagnosed with anemia; 5 belong to the group with unfavorable evolution;
- 12 patients diagnosed with type II diabetes; all 7 patients constituting the group with unfavorable evolution had type II diabetes.

Regarding the blood glucose values at admission, out of the 12 known patients with type II diabetes, the only values corresponding to the normal range (70 - 110 mg/dl) were recorded in 2 patients belonging to the group with favorable outcome, respectively 85 and 93 mg/dl. The rest of the patients, more precisely the 3 remaining patients of the group with favorable outcomes and the totality of the patients that formed the group with unfavorable prognosis registered glycemic values higher than the normal range.

The tendency was of aggregation of high glycemic values, with small exceptions, in the group with unfavorable evolution.

Upon admission, 9 of the 17 hospitalized patients presenting with the inflammatory syndrome. Of these, 5 patients had a favorable follow-up.

DISCUSSION

The heterogeneity of the studied group lies both in the variety of types of lesions for which vacuum therapy was chosen, and their pathological personal history.

It was noted that the shortest duration of hospitalization, as well as the lowest value of blood glucose at admission, were found in patients belonging to the group with favorable evolution, while their maximum values belonged to patients in the group with unfavorable evolution. This similar pattern of distribution of maximum and minimum values can offer a prediction of the number of hospitalization days based on blood glucose at admission. However, the result obtained was not statistically significant, the value of blood glucose at admission explaining only 0.5% of the number of days of hospitalization and the hypothesis that the value of blood glucose at hospitalization is a predictor of the prognosis of patients has not been confirmed. On the other hand, the statistical results obtained suggest that the glycemic value explains 17% of a patient’s evolution.

For a better understanding of the factors involved in guiding the evolution towards a favorable or unfavorable outcome, the second part of the study focused on a succession of 5 case presentations. All the selected 5 patients presented lesions with persistent or even worse follow-up under NPWT, the evolution as a whole of each case lying on the background of various comorbidities.

Regarding the first 3 cases, we present the outcome of 3 male patients with the ages of 53, 58, and 47 years, respectively. All these cases presented chronic lesions located in the lower limbs, as well comorbidities with significant resonance on blood perfusion: type II diabetes, LLOA, anemia (case 1 and case 3). In all 3 cases, the presence of LLOA is an important issue in the healing process of the lesions, which is why its solution by intervention or surgery plays a crucial role in the management process along with other surgical interventions and NPWT.

Unlike the cases presented above, case 4 is characterized by the vital risk of the associated pathology with which the patient presents, namely generalized peritonitis secondary to a revived, imprisoned multisacular eventration, complicated by strangulation, torsion, and necrosis of the intestinal loops. The patient's prognosis is impacted by the purulent post-operative wound, with a dragging character despite the NPWT applied. Regarding the unfavorable outcome of this case, we have to mention that in addition to the multiple comorbidities (type II diabetes, stage II hypertension, osteoporosis, bilateral gonarthrosis) and multiple personal pathological surgical histories (thyroidectomy, appendectomy, myomectomy, intestinal occlusion) in this case, the particularity emerges from the coexistence of short bowel syndrome and anorexia nervosa. Short bowel syndrome is the prerogative of an extensive surgical bowel section that involved subtotal enterectomy [23]. Anorexia nervosa is a complex behavioral and psychiatric pathology [24]. It is impressive how the two pathologies are intertwined and maintained an altered biological status of the patient, burdened by dehydration and electrolyte and acid-base disorders. All these overlapped with metabolic disorders caused by an unbalanced type II diabetes lead to a status of severe malnutrition. This context, associated with anemia, deprives the whole body, including the postoperative wound of nutrients needed for healing. One mechanism by which NPWT promotes the healing process is by increasing local blood flow, so implicitly the supply of oxygen and nutrients, but the beneficial effect is canceled if the blood flow to the wound is poor in oxygen and deprived of nutrients [25].

In selected case 5, the patient presents for a parietal suppuration in the right inguinal region after surgery with alloplastic materials for the right inguinal hernia. The patient's personal history includes an evacuated inguinal parietal abscess, which occurred after the surgical correction of the right inguinal hernia. In terms of comorbidities, the pathologies representative for the group with unfavorable evolution, respectively diabetes and anemia were noted. In addition, cardiovascular abnormal findings and a prostate adenoma were diagnosed. In the management process, an abscess underlying the pubic symphysis is identified. Surgical treatment aimed to remove all the debris and a cartilaginous fragment, subsequently applying NPWT to the semi-open wound. The patient was discharged healed and in good general condition.

At the first follow-up visit, the patient presents with a dehiscent wound with a visible granulation process and with a good general condition. However, at the second reevaluation, the biological and clinical condition of the patient was significantly worse (presence of fever and inflammatory signs), the right inguinal region appeared pasty and edematous, with the suppuration area located at the inferior area of the wound. Imaging results (inflammatory phenomenon extended to the muscle groups adjacent to the suppurative process, multiple lymphadenopathies, densification of subcutaneous inguinoscrotal and bilateral gluteal tissue, the osteolytic appearance of pubic bones) corroborated with other clinical and paraclinical investigations outlined the diagnosis of pubic osteitis. This diagnosis placed the case on a higher hierarchy in terms of gravity. It is to note that under conservative treatment the symptomatology diminished.

In an attempt to understand the unfavorable evolution of the patient, certain aspects should be discussed. First, the patient was the oldest from the study group (80 years) and the specialty literature mentions the alteration of healing processes in the advanced senescence process [4, 20, 21]. Secondly, there were various comorbidities, of which poorly controlled diabetes, which is responsible for the management difficulties of traumatic wounds. In addition, the infectious factor must be brought into question - staphylococcus aureus was isolated from the patient's wound – a virulent pathogen that causes treatment difficulties, even in people without a significant amount of comorbidities.

There are several limitations of this study that should be mentioned. One of these is the small number of patients included. Also, the study was retrospective and the data were collected from indirect sources, namely the computer database of the hospital, with no information available regarding the materials (filler material, wound contact layers) and the functional parameters applied (pressure level, pressure regime, vacuum source). Certain biological parameters crucial for documenting the prognosis of the case could not be identified, for which reason it was not possible to include them in the statistical analysis.

CONCLUSIONS

According to our study results, the majority of patients for which negative pressure wound treatment was applied presented a favorable outcome.

In order of frequency, the diagnoses at admission for patients included in our study were as follows: gangrene with various localizations in the lower limb, local complications of postoperative wound, legs trophic ulcers, secondary purulent peritonitis, necrotizing fasciitis, and parietal-abdominal cellulitis.

The average number of hospitalization days for the group with unfavorable outcomes was almost double compared to that of the group with favorable evolution, which engaged higher costs.

Pathologies such as diabetes, lower limb obliterative arteriopathy, and anemia had a prevalent distribution in the group with unfavorable evolution. According to the statistical analysis, the glycemic value can predict 17% of a patient's prognosis scenario (favorable/unfavorable).

The cases presented in the study mean to highlight the importance of an immediate, integrative and exhaustive therapeutic approach. Although an extremely promising therapeutic option, NPWT can prove to be disappointing, given its impact in the background of suboptimally managed comorbidities.

New anatomical landmark for rotational assessment of total knee arthroplasty

Bogdan Crețu[1,2], Bogdan Șerban[1,2], Sergiu Iordache[1,2], Adrian Cursaru[1,2], Mihai Costache[2], Cătălin Cîrstoiu[1,2]

Abstract: *One of the most controversial topics in total knee arthroplasty is rotation of the femoral component. The current gold-standard in total knee arthroplasty consists in positioning the femoral component in 3 degrees of external rotation to the epicondylar axis, having as reference the tangent to the posterior condyles. Achieving the correct rotation of the femoral components is one of the main goals during total knee arthroplasty. Multiple complications can result from internal femoral rotation, such as lateral patellar tilt, patellar subluxation or dislocation, mobilization with movement on pain, and low survival rates of the femoral components. Postoperative rotational assessment of protective components can only be performed correctly using computed tomography. The known evaluation methods are related to anteversion of the femoral neck, femoral trans-epicondylar line, insertion of the posterior cruciate ligament from the tibia and tibial tuberosity. The purpose of this study was to evaluate the rotation of the prosthetic components in the group of patients with the methods validated by studies and to find alternatives to evaluate the rotation of the femoral component. Thirty-four patients diagnosed with gonarthrosis, proposed for total knee arthroplasty, were included in the study. This is a prospective cohort study in which applied statistics consisted of analyzing data using frequency and percentage for qualitative and mean variables and standard deviation for quantitative variables.*

Keywords: *total knee arthroplasty, femoral component rotation, posterior condylar angle, linea aspera*

INTRODUCTION

Rotation of the femoral component is one of the most controversial topics in total knee arthroplasty [1]. From the preoperative assessment required to determine the rotation of the femoral condyles relative to the hip and knee followed by the intraoperative decision to position the femoral component in a slight external rotation to the trans epicondylar axis and to the postoperative evaluation of the rotation, all these are subject to controversies of analysis and decision that may represent another factor of error in the postoperative evolution of the patient [2].

The current gold-standard in total knee arthroplasty consists in positioning the femoral component in 3 degrees of external rotation to the epicondylar axis, having as reference the tangent to the posterior condyles. This is a surgical move that will place the femur in a slight external rotation. It is said that this surgical move will minimize the possible complications as patello-femoral/femoro-tibial movement and arthroplasty survival over time.

Postoperative rotational assessment of protective components can only be performed correctly using computed tomography. The known evaluation methods are related to anteversion of the femoral neck, femoral trans-epicondylar line, insertion of the posterior cruciate ligament from the tibia and tibial tuberosity. If the two femoral epicondyles are difficult to identify on CT scans even with software for removing metal artifacts, it was decided to introduce new signs of rotational CT analysis, which materialized through the linea aspera as a radiological landmark.

Achieving the correct rotation of the femoral components is one of the main goals during total knee arthroplasty [3].

The proper alignment of the femoral component during total knee arthroplasty is a crucial step that influences postoperative results. The position of the femoral

component in the axial plane is responsible for flexion stability, knee joint kinematics, flexion alignment, and patellar tracking.

Complete axial plane measurement before and after total knee arthroplasty can only be performed using CT scans. For a proper assessment of total knee arthroplasty, the spread of metal artifacts should be reduced and anatomical signs should be properly identified, which is sometimes difficult to achieve mainly for the two femoral epicondyles. Linea aspera is an anatomical sign that is constant and it is not influenced by metal artifacts.

The purpose of this study was to evaluate the rotation of the prosthetic components in the group of patients with the methods validated by studies and to find alternatives to evaluate the rotation of the femoral component.

The study focused on comparing the standard evaluation of femoral component rotation was performed using the posterior condylar angle (PCA) with a new sign that is using the linea aspera ridge and the Akagi line was used for the rotational evaluation of the tibial component [4]

MATERIALS AND METHODS

Thirty-four patients diagnosted with gonarthrosis, proposed for total knee arthroplasty, were included in the study. All the patients analyzed were from the orthopedics and traumatology clinic of the Bucharest University Emergency Hospital during 2018-2019. The study was approved by the hospital's ethics commission in compliance with international research ethics standards. The following angles were measured using CT scans: the angle between a tangent to the posterior condyles and the surgical trans-epicondylar axis (surgical TEA) called the posterior condylar angle (PCA) (Figure 1), the angle between a tangent to the posterior condyles and the tibial component axis (Akagi line) (Figure 2) for rotational assessment of the tibial component.

The posterior condylar angle was compared with a new sign (Figure 3) measured preoperatively and postoperatively as follows: 15 cm proximal to the joint line, is identified and circumscribed in a circle linea aspera, the femoral shaft is also circumscribed in a circle, and the center of the two circles describes a line and the angle between this line is called the linea aspera and a tangent to the posterior condyles was called the aspera condylar angle (ACS) preoperative and postoperative.

This is a prospective cohort study in which applied statistics consisted of analyzing data using frequency and percentage for qualitative and mean variables and standard deviation for quantitative variables. The ANOVA test with repeated measurements was also used to compare the different variables, as well as the Pearson test to verify the correlation between the variables.

Figure 1: Tangent to the posterior condyles

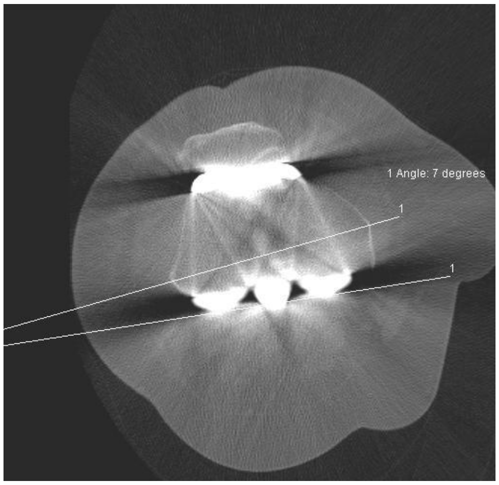

Figure 2: Akagi line

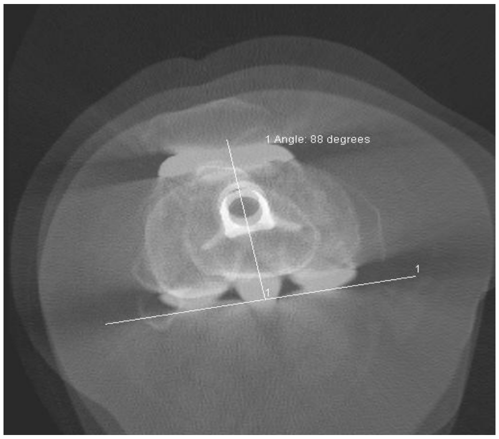

Figure 3: New landmark

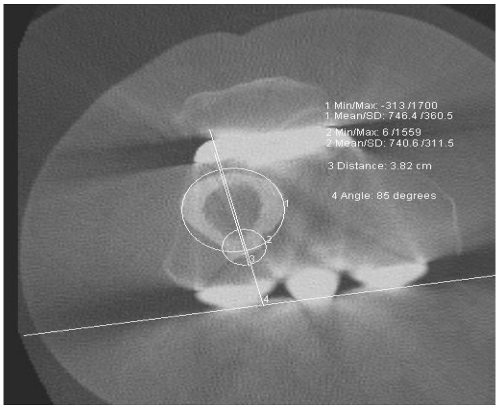

The landmark proposed for validation was evidenced following the steps: 15 centimeters proximal to the joint line, the linea aspera and the femoral shaft were identified. Both were framed in a circle and the centers of the two circles were identified, later joining the two identified points by a line, called the linea aspera. The purpose was to evaluate the angle made by the tangent to the posterior condyles (standard and easily identifiable sign) with this line in the preoperative and postoperative phases.

The main hypothesis of this study was represented by the complex evaluation of the rotation of the prosthetic components in a patient undergoing total knee arthroplasty to understand the clinical effects of malrotations.

RESULTS

Regarding to the degree of reliability of radiological measurements, it was rated from 1 to 5, 5 representing the highest degree of confidence. There is a percentage of 45.71% of specialists who gave a degree of confidence 5, followed by a degree of confidence 4 (37.14%) and a degree of confidence 3 (17.14%).

Regarding to the quality of the acquisition of radiological images, it was rated from 1 to 5, 5 representing the highest degree of confidence: a percentage of 51.43% gave 5, equal to 3 and 4 (20%) and 8.57% gave 2.

Table 1: Average values of the new landmark in the preoperative-postoperative and PCA phases

		New preoperative reference	**New postoperative reference**	**PCA**
No.	Valid data	35	35	35
	Missing data	0	0	0
Average		89.3400	93.1309	3.1034
Standard deviation		12.28395	12.37648	1.70943

The average values of the quantitative variables are depicted in Figures 4, 5 and 6.

Using the Pearson test, there is a statistically significant and strong correlation between the new preoperative reference and the new postoperative reference (r = 0.98, p = 0.001). There were no statistically significant correlations with PCA.

Applying the Anova test with repeated measurements, it was concluded that there is a statistically significant difference in the evolution of the new sign in the preoperative phase and the postoperative phase (p = 0.001, 89.34 vs. 93.13).

Using the ANOVA method, there were no statistical differences in the level of specialists who awarded the confidence levels and the new preoperative sign, the new postoperative sign and PCA, who had similar averages.

Figure 4: Distribution of the new preoperative reference. The average value of the new preoperative reference is 89.34 (12.28)

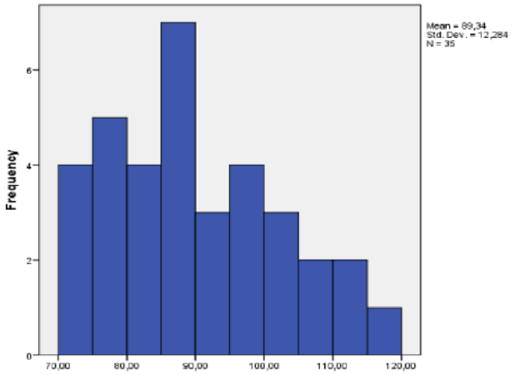

Figure 5: Distribution of the new postoperative reference. The average value of the new postoperative reference is 93.13 (12.37)

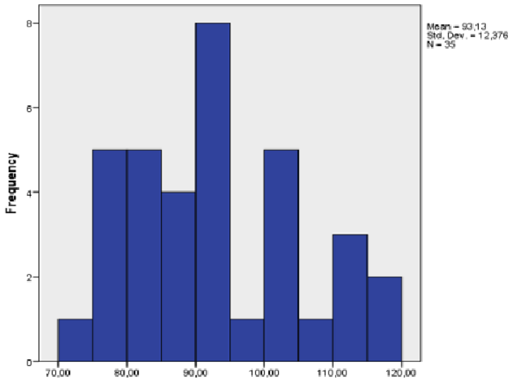

Figure 6: PCA distribution. The average PCA value is 3.10 (1.70)

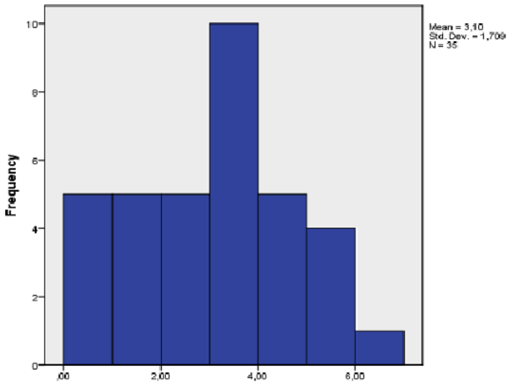

Using the ANOVA method, there were no statistical differences in the level of specialists who assessed the quality of the acquisition and the new preoperative sign, the new postoperative sign and PCA, which had similar averages.

DISCUSSION

Establishing the proper rotation of the femoral component is unanimously accepted as an important point to achieve in total knee arthroplasty. As Mochizuki pointed out more than

30 years ago, the correct rotational positioning is in a slight external rotation [5].

Table 2: Correlations between the new preoperative and postoperative references and PCA

		New preoperative reference	New postoperative reference	PCA
New preoperative reference	Pearson correlation	1	0.982 **	-0.274
	p		0.000	0.111
	No.	35	35	35
New postoperative reference	Pearson correlation	0.982 **	1	-0.218
	p	0.000		0.209
	No.	35	35	35
PCA	Pearson correlation	-0.274	-0.218	1
	p	0.111	0.209	
	No.	35	35	35

Multiple complications can result from internal femoral rotation, such as lateral patellar tilt, patellar subluxation or dislocation, mobilization with movement on pain, and low survival rates of the femoral components [6].

Also, an internal femoral rotation will increase the laxity in the lateral compartment during flexion, varus deviation and unfavorable clinical results [7].

Conversely, excessive external femoral rotation will result in poor functional results, and the patient will experience some degree of flexion instability.

Internal rotation of the femoral component combined with internal rotation of the tibial component are the leading cause of anterior pain after total knee arthroplasty [8].

Soft tissue rebalancing and femoral component rotation can be performed by the two known techniques: the measured resection technique and the “tension gap” technique (extension space equal to flexion space) [9,10]. A rotation of 3 degrees to the tangent to the posterior condyles is unanimously accepted in the technique of measured resection but not always perfect [11, 12].

In the case of the technique of measuring the extension and flexion spaces, it can be performed by two mechanisms: 1. the use of a conventional spacer, but there is no consensus on the tension that need to be applied; and 2. the use of blocks with predetermined dimensions that must be introduced in the two spaces, a maneuver that is strictly subject to the surgeon's experience and is not providing objective information regarding to the tensions in the two compartments [13, 14].

A randomized study comparing the two techniques states the superiority of using a mechanical spacer (laminar spreader) in a resection measured to establish an appropriate femoral rotation [15].

Intraoperative technique of rotational positioning of the femur is relatively standardized and well supported scientifically with prospective and randomized clinical trials. The superiority of one technique over another is not proven. Both techniques will position the femur in a slight external rotation which has proven beneficial for the vast majority of patients for both immediate and long-term results.

The rotational positioning problem for a small number of patients with low satisfaction rates, results from standardization itself, not taking into account the rotation of the femoral condyles relative to the femoral neck and the entire axis of the pelvic limb in the preoperative stage.

In the case of patients in whom a significant deformity of the entire pelvic limb can be observed during the standard preoperative assessment, radiological examination of the pelvis may reveal changes of coxa vara or valga type, an examination of the orthopantogram reveals an exaggerated femoral or tibial curvature, clinical examination indicates altered gait due to deformities and a CT scan of the entire pelvic limb may be recommended. This will evidence rotational changes that do not fall within the preoperative standard assessment and may impose intraoperative decisions specific to each patient.

Starting from the fact that the two femoral epicondyles needed to trace the trans epicondylar axis to measure the rotation of the femoral component are both difficult to identify in the preoperative stage but especially after prosthetic implantation due to metal artifacts, we searched and identified another anatomical sign, unchangeable for rotational assessment and specific to each patient.

CONCLUSIONS

Following the computed tomography analysis of the first patients admitted to the study, an initial conclusion was reached, namely that the evaluation of the rotation of the femoral component should be performed after the trans-epicondylar line, which is difficult to identify correctly on CT scans, even with removal of artifacts. It was concluded that it is necessary to find a new radiological sign for the rotational assessment of the femoral component.

For all cases included in this pilot study, the femoral component was placed intraoperatively at 3 degrees of external rotation relative to the posterior condyles. The analysis of the new radiological sign evidences the external rotation of the femoral component, when it is performed taking as a sign the tangent to the two posterior femoral condyles.

Linea aspera has proven to be a reliable and useful anatomical sign for measuring the rotational positioning of the femoral component in total knee arthroplasty due to its constant position and because its identification is not obstructed by metal artifacts.

This new sign can be used in the same patient in the preoperative and postoperative phase, using CT examination. However, no correlation could be identified with the established assessments between the values obtained from the measurements, a correlation possible only in much larger studies, with larger patient groups.

It has been proposed to use this sign for radiological analysis of total knee arthroplasty in patients in whom preoperative CT examination is performed due to major axis deformities or bone stock deficits, followed by postoperative CT analysis.

The high variability of the linea aspera compared to the posterior condyles in the preoperative evaluation evidences the rotational complexity of the knee and the need for in-depth knowledge of its kinematics in relation to the entire pelvic limb.

The results of the measurements with the help of the proposed new sign show that it can be used in extreme cases in the rotational assessment of the femoral component.

New approaches regarding the protection forces’ health against the effects of some toxic substances

Pavel Otrisal[1], Camelia Diaconu[2], Ovidiu Bratu[3], Florentina Ionita Radu[3], Zdenek Melicharik[4], Simona G. Bungau[5]

Abstract: *In the past, finding out the chemical resistance of the barrier materials designated for the production of individual protective equipment ofthe protection forces (policemen, firefighters, soldiers) was based on the need to respond to protection against weapons of mass destruction. Simple chemical methods based on indicating the colorimetric reactions were used. It was necessary to switch to more universal methods due to a change in the security of the environment and the need to focus on toxic industrial materials. The universality is due to using sensitive QCM sensors equipped with a special detection layer and some special carbon electrodes. The paper deals with new methods that are used to determine the chemical resistance of the barrier materials against the permeation of toxic substances, primarily in field conditions. However, they can also be used in stationary chemical laboratory conditions.*

Keywords: *Permeation, barrier material, PIEZOTEST, KONDUKTOTEST, SORPTEST*

INTRODUCTION

Public health is and must be a major interest for the policies and legislation of a country. Maintaining and improving it must be done by implementing appropriate measures and programs, by educating the population and by raising the standard of living. A particular sector within this field of health is represented by the health insurance of the protection forces (police, firefighters, soldiers). In addition to psychological training, physical training, proper nutrition, etc., they must be provided with the optimal equipment to cope with specific interventions. Exposure to various harmful factors (fire, extreme heat, chemicals, pollutants of all kinds, etc.) must take place in the optimum parameters, ensuring the best performing materials, with maximum level of protection [1]. Direct contact with these substances (drugs, chemicals, flammable substances, poisons, narcotics, various medical and pharmaceutical waste) [2-4] which can usually be found in nature and especially in cases of emergency (fire, war, explosions) can often be lethal, through harmful compounds that are released or which, in direct contact with the skin can cause severe burns, major infections, dizziness, fainting, headache, choking, serious pathologies as cancer [5, 6] etc., and finally – death.

The interest to produce protective materials impervious to possible contamination agents has increased in recent years. The political decision makers, as well as the economic agents and the manufacturing companies (that are producing harmful substances, pollutants, as well as those who's

activity field involve obtaining the performant barrier materials) concentrate their activity more and more intensely on this aspect of the development of the protective equipment with high quality, reduced cost, with high demand on the market and which generate waste as little as possible following the production process [7-14].

In the last decade, there has been a shift from relatively simple chemical colorimetric methods for testing the resistance of the barrier materials against the permeation of toxic substances to sophisticated methods based on a principle of sensor technologies [15-21]. This change was called by a gradual re-evaluation of the security threats experienced by military professionals in military operations [22, 23]. Representatives of the North Atlantic Treaty Organization declared that high use of weapons of mass destruction is currently unlikely [24]. Industrial chemicals are now considered to be a significantly more important security threat because their leakage can cause many losses and can cause contamination of large areas of interest [25, 26]. New methods that enable the testing of the chemical resistance of the barrier materials against the permeation of toxic substances find their practical application also in testing of already established final products and also of the barrier materials that may find their use in the future [27, 28]. New methods also allow very fast evaluation of the permeation data found and meet all requirements set by military and European standards [29]. The concept of research, development, and production of permeation devices using sensor technologies has been designed to meet the requirements for their use in field conditions and to enable obtaining permeation data with minimal attendance and service [30-32].

All these aspects have led to a gradual decrease in the efficiency of work with colorimetric methods, applicable only for determining the chemical resistance of toxic substances (used in wars) under simulated laboratory conditions. These methods did not allow a detailed analysis at the level of the North Atlantic Treaty Organization nor at the European Union level.

PIEZOTEST method

The PIEZOTEST method uses a QCM (Quartz Crystal Microbalance) based piezoelectric sensor to detect permeated toxic substances. These sensors, which find their application in many technical and industrial applications, have been modified to detect the permeation of the toxic substances through the barrier materials by applying the appropriate detection layer to guarantee the functionality of this sensor as a gravimetric detection device. The 1 Hz sensor's response is reported to correspond to the detection of 1 ng of a toxic substance. This sensitivity is quite enough for operating the measuring device in both field and laboratory conditions. Application and software equipment, which is an integral part of the measuring equipment, allows on-line monitoring of a wide range of standardized parameters. The most important data is the breakthrough time (or also the resistance time) when the permeation mass's (cumulative amount) value is reached for a particular (subtracted) value based on the permeation mass (cumulative mass) versus time graph. However, it can also be specified as the normalized breakthrough time, but only if it relates to the normalized permeation weight (cumulated amount) specified by the relevant standard. For fast data evaluation without the need for application and software equipment, it is possible to use the value of protection time (chemical resistance time) expressed as lag-time, to which the value of diffusion coefficient is automatically recalculated. The time to reach the maximum permeated concentration, which is sometimes referred to as the time of half diffusion flow, is also significant for the purposes of assessing the capture efficiency of the test chemicals through barrier materials. The permeation calculator automatically recalculates the value of the respective diffusion coefficient to this value, which creates a space for comparing the penetration rate of the test chemical through the tested barrier material. The time to reach the maximum permeation rate (when the lag-time is reached) and the maximum reached permeation rate (when the steady state permeation rate is reached) is very important for the evaluation of the breathable barrier materials is very significant. Results of the calibration measurements showed that it is possible to achieve high-quality dependencies of the QCM sensor working frequency increase, thus the concentration of test chemical over time, even though this method was not primarily intended as analytical.

KONDUKTOTEST method

The KONDUKTOTEST method is based on the basic analytical method working on electrochemistry, thus dissociation of ions. It introduces practical knowledge of conductometry into the implementation testing practice and adapts them to the conditions for determining the chemical resistance of barrier materials against the permeation of toxic substances. A significant benefit of the used measuring device is the replacement of very expensive platinum electrodes with glass electrodes. These electrodes are characterized by a very good sensitivity and minimal maintenance and operation requirements. Their further advantage is that they do not experience problems with memory effect, which is an important and limiting factor for the electroanalytical methods. The elimination of this effect is based on the actual needs of measurement when working with very dilute solutions. In practice this means that a very low concentration of dissociated ions is sufficient to form a permeation curve, which serves as a basis for the reading of standard values. This concentration is so low that it does not produce the memory effect of the used carbon electrodes even after their repeated use. The KONDUKTOTEST method uses the dependence of electrical conductivity increaseover time to generate the resulting permeation data and evaluate the effectiveness of barrier materials to withstand to a direct contact with toxic substances. The other standard values are the same as in the previous case. The results of the calibration measurements confirmed the theoretical considerations associated with classical conductometry, which in practice means that high quality results have been achieved.

SORPTEST method

The SOPRTEST method suitably complements the abilities of the above two methods. Its primary use can be seen to determine the chemical resistance of barrier materials under dynamic conditions. Due to the combination of the conductometric measurement and the measurement based on the use of QCM sensors, a unique device has been constructed. It enables the combination of methods and used barrier materials. The permeation cells can be adapted to the particular type of measurement and the test material. In addition to breathable and insulating barrier materials, the sorption properties of the bulk sorbent layers can also be tested. By partial modification of the measuring system it is also possible to characterize filters of protective masks and thus to study their dynamic and static sorption capacity. The source of the gas phase of the test chemical is a test tube fitted with a Peltier´s cooler (condenser). The device enables continuous regulation of air flow during its use within calibration, actual measurement and desorption of QCM sensor. Before starting and during the measurement, it is possible to adjust the temperature, which ensures the transfer of the test chemical into the gas phase and the temperature of the Peltier´s cooler. Permeation measuring cells are tempered separately. A biological incubator has proved to be a suitable device. The SORPTEST measurement device allows the generation of the same standardized permeation data. This approach respects the principle of comparability of the observed permeation data across the older used measurement methods. Application and software equipment of this device enables creation of an output report from measurements. It includes results of calibration measurements and individual graphs characterizing the course of monitored standard quantities. The report also includes data concerning the chemical test that was used, its basic tabulated characteristics and toxicological data.

CONCLUSIONS

Obtaining permeation data characterizing barrier materials in accordance with European standards enables their unambiguous description not only at the national level but also at the European level.This approach will allow describing the barrier properties not only during their use, but also during their development and quality verification. The combination of methods for the implementation the knowledge of physics, sensor technologies, classical analytical chemistry and toxicology has resulted in the construction of very modern and sophisticated measuring systems that meet the highest demands on the quality of the obtained data while maintaining economic rationality.

INTRODUCTION & BACKGROUND

Non-melanoma skin cancer (NMSC) comprises squamous cell carcinoma (SCC), basal cell carcinoma (BCC), and several rare skin tumors (i. e. Extramammary Paget’s disease), being the most common malignancy affecting people worldwide. It represents the majority of skin cancers and a significant percentage of all malignancies. Despite increasing public awareness and scientific interest, the incidence of NMSC is constantly increasing. Even though most NMSC`s are associated with less aggressive behavior, they can still be invasive locally and cause extensive damage to neighboring structures, inducing significant morbidity. Also, different types and subtypes of NMSC tend to have frequent recurrences and may have significant metastatic potential. As a direct consequence, NMSC has become an important issue for healthcare systems with a significant socio-economic impact.

EXTRAMAMMARY PAGET’S DISEASE (EMPD)

EMPD localized to the vulva is a rare disease that canmimic different types of dermatosis and only four cases havebeen reported in our practice in the last 5 years.

Definition

EMPD, according to World Health Organization, is a rare intraepithelial neoplasm characterized histopathologically by a prominent growth of large cells, with apocrine or eccrine glandular-like pattern, originating in the skin (primary EMPD) or representing intraepithelial spread of a hidden visceral carcinoma (secondary EMPD). This type of disease is represented by the International Classification of Diseases for Oncology with the following code: 8542/3. [1, 2]

EMPD is a marginated plaque that clinically and histologically

resembles Paget's disease, but occurs in sites rich in apocrine glands, such as vulva, anogenital region and axilla. Currently, there is controversy as to how often this condition appears against on the background of an underlying carcinoma and how often it occurs primarily in the epidermis or apocrine ductal tissue in the affected area. This gave rise to the concept of primary and secondary extra-mammary Paget's disease [3, 4].

Epidemiology and Etiology

EMPD accounts for about 1 % of all ano-genital neoplasms. It develops more frequently in Caucasian women in the postmenopausal period [1] and usually begins in the fifth decade or later. Current opinion is that, in about 75% of cases, extracellular Paget's disease appears as a primary intra-epidermal neoplasm, possibly from ductal cells of the apocrine gland or keratinocyte stem cells. Another possible origin may be the Toker's cells [3, 5]. In the remaining 25% of cases, there is a hidden primary adenocarcinoma. These cases are referred as secondary Paget's disease.

Only a few cases of association between mammary and vulvar Paget's disease have been described. Under extraordinary circumstances, EMPD is a secondary event caused by extension of an adenocarcinoma either of the rectum to the perianal region, or of the cervix to the vulvar region. On the other hand, genital Paget's disease with a long evolution, can extend into the cervix and urinary tract [6].

Localization

The labia majora is the most widespread site, followed by the labia minora and clitoris. The perineum, perianal area, scrotum, penis, lower abdomen and inguinal folds can also be affected [1].

Based on origin, several classification schemes have been proposed [22] :
Type 1: primary vulvar cutaneous origin
Type 2: secondary to primary anal or rectal adenocarcinoma
Type 3: secondary to urothelial carcinoma

OR

Type I: Paget disease of primary cutaneous origin
Ia: as a primary intraepithelial neoplasm
Ib: as an intraepithelial neoplasm with invasion
Ic: as a manifestation of underlying adenocarcinoma of skin appendage or vulval glandular origin
Type II: Paget disease of noncutaneous origin
IIa: secondary to anorectal carcinoma
IIb: secondary to urothelial neoplasia
IIc: as a manifestation of another noncutaneous carcinoma: endocervical, endometrial or ovarian adenocarcinoma, etc.

Clinical features

The most common presentation is a relatively well-demarcated flat or slightly elevated, scaly, erythematous patch or plaque, accompanied by itching or burning, often simulating eczema. Unusual forms include lesions with hyper- or hypopigmentation and multi-centric bruising [1].

EMPD lesion has many features in common with Paget's disease of the nipple. The edges are sharp, rounded and slightly raised, and includes an area that is pink or red. The affected area may be tiled, and small, gray-colored crusts may cover erosion. Itching is an essential feature and there may be excoriations or lichenification. Areas of fluctuating hyperpigmentation may be present, causing confusion between extra-mammary Paget's disease and superficial spread melanoma. In some cases, leukoplakia may be present [3, 7, 8, 9].

The clinical presentation of the disease varies by site, the most frequent involved being vulva. The first symptom, especially in vulvar lesions, is itching and burning, which can be persistent and growing. It is often seen as dermatitis and may be disturbed by topical therapy. The surfaces of the lining of the labia are periodically redder than the skin when both areas are involved, and the change may proliferate towards the thighs, mons pubis and vaginal introitus. There will be a limited papillomatous area. Characteristic clinical features include fierce advancement, challenging all local applications, and the whetted margin. Eventually, one area may become thickened and ulcerated as evidence of downwards invasion. Lymph nodes involvement or distant metastases can appear. Although most cases of primary carcinoma result from a hidden adenocarcinoma of the sweat gland, it is essential to examine the patient for evidence of a later adenocarcinoma hidden in the cervix and rectum [3].

Pathogenesis

Histogenesis of primary EMPD is unknown [1].

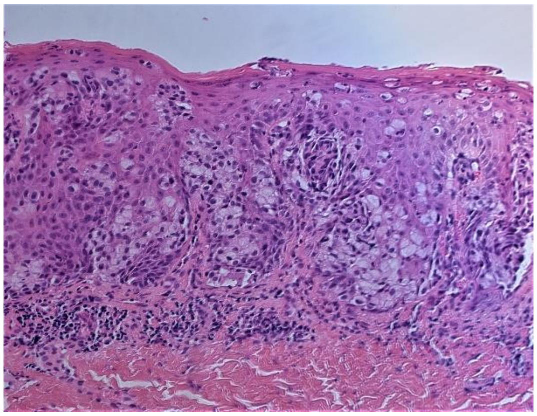
Paget cells in the epidermis may appear as an in situ upward extension of an adenocarcinoma located in the deeper glands. Alternatively, EMPD may have a multifocal primary origin in the epidermis and skin appendages, and does not represent an epidermotropic spread or metastasis from an intrinsic carcinoma of the sweat gland. It can be shown that almost 25% of EMPD originates from primary adenocarcinoma of the secretory glands. Primary tumor and Paget cells are usually mucus secretory [10].

At one point, it was widely accepted that in primary EMPD, Paget cells in the epidermis are due to an in-situ upward extension of an in-situ adenocarcinoma of the sweat glands along the eccrine or apocrine ducts. This theory is comparable to the generally accepted view that secondary EMPD shows an extension of a cervical, rectal or urinary adenocarcinoma and that the progression of Paget breast disease is an extension of a lactiferous canalicular epidermotropic carcinoma. The fact that a hidden adenocarcinoma often could not be demonstrated, can be explained by the different anatomic characteristics between the breast, which has only 20 large, conspicuous lactiferous ducts, and the genital skin, which has thousands of small apocrine and eccrine glands, making the localization of this particular small gland invaded by carcinoma increasingly difficult [6].

Histopathology

EMPD disease has in common with Paget's disease the presence of varying numbers of Paget cells within the epidermis (Figure 1). In some cases, the Paget cells are found to be limited to the acanthotic epidermis, accompanied by hyperkeratosis, parakeratosis, erosion or ulceration. Frequently, Paget cells can be identified within the epithelium of hair follicles or eccrine sweat ducts. This types of in situ malignancy associated with EMPD has the same favorable prognosis as EMPD limited to the epidermis. However, the prognosis is much worse in cases in which the Paget cells have invaded the dermis from the epidermis or from an underlying sweat gland carcinoma. Glandular clusters with a central lumen, absent in mammary Paget's disease may be identified in the lower epidermis in extra-mammary Paget's disease [6].

Figure 1: EMPD. Paget cells in epidermis (photomicrograph taken from our cases), hematoxylin &eosin, magnification 200x



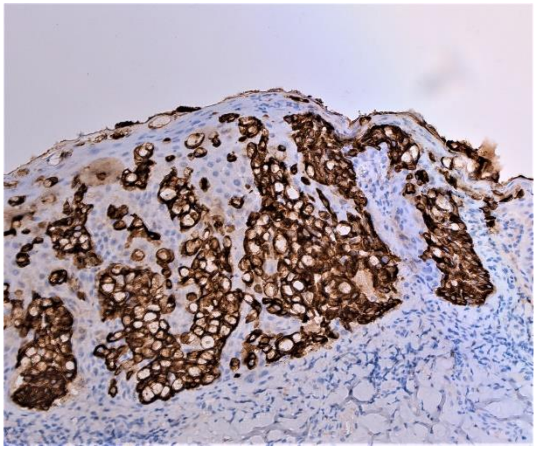
Serial sectioning of excised lesions of vulvar EMPD demonstrated that the lesions within the epidermis and its appendages have a multifocal origin. In the cases that have extensive epidermal lesions, the involvement of eccrine glands and ducts is occasionally, and the involvement of apocrine glands and ducts is absent, even if some Paget cells form apocrine glandular structures in the epidermis. Despite the existence of cohesion between the epidermal and the ductal foci, no one can definitive say that the extension is in an up or down direction. The dermal invasion in EMPD has its beginning point in the epidermis and not ductal or glandular structures.

The origin of the Paget cell may be the poral portion of an apocrine duct, or the pluripotential germinative cells within the epidermis [6]. Paget cells have an abundant basophilic to amphophilic cytoplasm and vesicular nuclei with pronounced nucleoli. They are generally distributed in a solitary fashion or may form gland-like structures or well-demarcated solid nests. Involvement of adnexa (hair follicles and eccrine ducts) is seen in most cases. Rarely, single cells, glands and solid nests can be found in the dermis; this is considered to be microinvasion. Dermal invasion is rare in vulvar EMPD, more common in perianal region. However, this type of microinvasion cannot be applied in cases that are associated with an underlying adenocarcinoma with a ductal in-situ component [1].

Immunohistochemistry

Immunohistochemical staining shows that Paget cells stain consistently positive for CK7 (cytokeratin 7) [1] (Figure 2) and EMA (Epithelial membrane antigen) – used by pathologists like a marker of Paget disease [11] (Figure 3).

Figure 2: Paget cells showed positivity for CK7 (cytokeratin 7also called as keratin 7, CK7, KRT 7, K7) (photomicrograph taken from our cases), magnification 200x



Paget cells often express GCDF-P15 (gross cystic disease fluid protein) (Figure 4), ERBB2 (HER2/neu) (Figure 5), CEA (carcynoembrionic antigen), CA125 (cancer antigen 125/ MUC16), and AR (androgen receptor) [1].

Figure 3: Paget cells showed positivity for EMA (epithelial membrane antigen also known CD227, MUC1 or episialin) (photomicrograph taken from our cases), magnification 200x

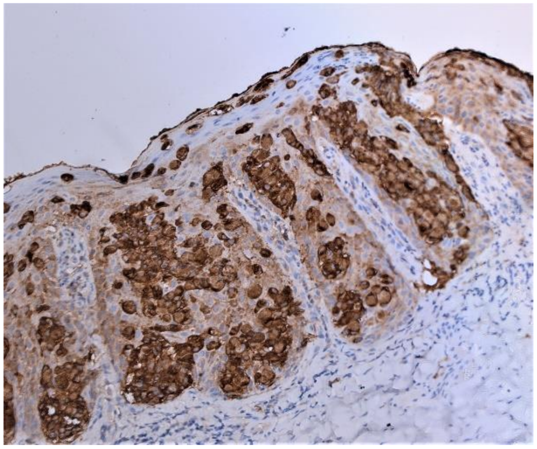


Figure 4: Paget cells showed positivity for GCDFP-15 (gross cystic disease fluid protein also known BRST2, PIP-prolactin induced protein) (a photomicrograph taken from our cases), magnification 200x

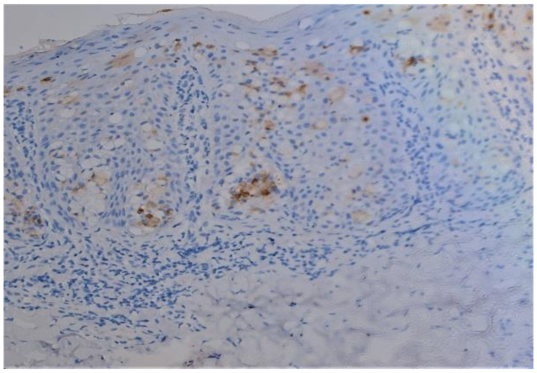

Figure 5: Paget cells showed positivity for ERBB2 (human epidermal growth factor receptor 2, also known HER2/neu, c-erbB2, CD340)(photomicrograph taken from our cases), magnification 200x

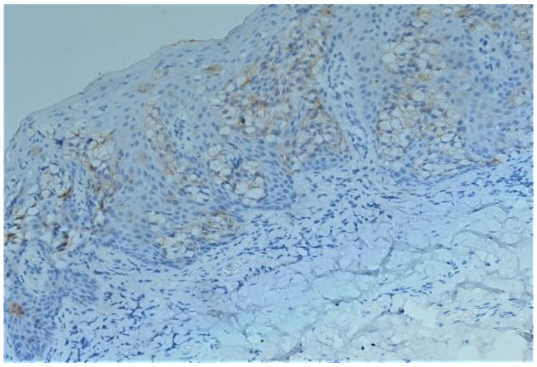


Differential diagnosis.

For correct diagnosis, immunohistochemistry and clinico-pathological correlation are essential [1].

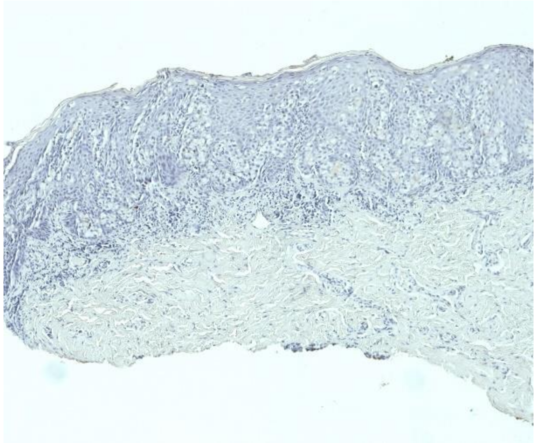
The most pressing matter is distinction between primary and secondary EMPD (Table 1). Potential imitators of EMPD are Toker vulvar cells, vulvar and penile analogues of cervical stratified mucin-producing intraepithelial lesion, high-grade squamous intraepithelial lesion, melanoma, pagetoid dyskeratosis, and clear cell papulosis. [1]

Table 1: Differential diagnoses of Extra-mammary Paget's disease (Immunohistochemical Markers). [12]

Immuno-histochemical marker	Primary extra-mammary Paget's disease	Secondary extra-mammary Paget's disease	Bowen's disease	Superficial spreading melanoma
CK7	+	+	+ or -	-
EMA	+	+		
CEA	+	+	-	-
GCDFP-15	+	-	-	-
Melan-A	-	-	-	+
P63	-	-	+	
S100 protein	-	-	-	+
HMB45	-	-	-	+

For differential diagnosis with superficial spreading melanoma we currently use as immunohistochemical markers S100 protein and HMB45 (Figure 6), and we do not use Melan-A because it has often given false positive results (Figure 7).

Figure 6: Paget cells showed negativity for HMB45 (Human Melanoma Black) (photomicrograph taken from our cases), magnification 100x



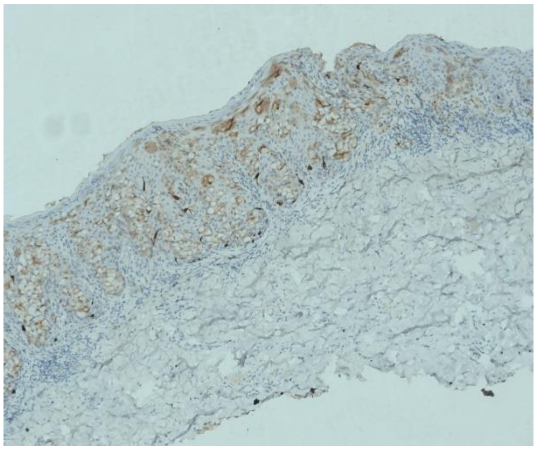
For proper localization of a large perineal lesion (vulvar or perianal) we usually use GCDFP-15 (positive for vulvar localization) and CK20 (positive for perianal localization) [13]

Prognosis and treatment

Primary EMPD's prognosis generally is better than that of mammary Paget's disease [6].

Local recurrence is frequent, even in cases with a wide surgical extraction, the recurrence rate being 12-58%. This may be related to positive surgical margins, skip areas, and multicentricity.

Figure 7: Paget cells showed false positivity for Melan-A (Melanoma Antigen, also called MART-1 – Melanoma Antigen Recognized by T cells 1)(photomicrograph taken from our cases), magnification 100x



Adverse prognosis is associated with increased serum levels of CEA and the depth of invasion. Proper tissue sampling and other investigations are vital to determine if there is an associated underlying malignancy that requires surgical excision. If such a malignancy exists, it should be excised along with all clinically abnormal epithelium. If no underlying malignancy is clinically and surgically detected on careful examination, the entire affected area of skin should be excised.

In the case of primary EMPD associated with an invasive component, the prognosis is significantly worse, and it can undergo lymph node metastasis. Cases with gene mutation of PIK3CA and AKT1 are often invasive. [1]

An important method is “Mohs surgery” (microscopically controlled surgery) that minimizes the recurrence rate by carefully controlling excision margins of the tumor [14, 15, 16].

Photodynamic therapy is another important tool in the treatment of EMPD, but it requires larger series and longer periods of follow-up [17, 18].

Topical imiquimod has been used with good results in cases with limited disease [19].

Radiation therapy has been supported either as an adjuvant to surgical therapy [20] or as an alternative therapy for elderly patients in whom surgery may have a greater risk [21].

DISCUSSIONS

Because of the resemblance of the lesions in the EMPD with other dermatological conditions, it is important that the clinician always consider a possible diagnosis of EMPD, especially in the case of lesions in the genital and anal spheres.

Due to the false positive results that may appear at various markers used for the diagnosis of EMPD, the pathologist cannot always rely on immunohistochemical tests for differential diagnosis with other disorders. Therefore, a correlation between clinical, paraclinical and histopathological data is very important for a correct diagnosis.

CONCLUSIONS

EMPD is a very rare skin malignancy that needs to be diagnosed and treated accordingly [23]. Because it can mimic a lot of benign or malignant diseases, a correct differential diagnosis is crucial for the treatment and prognosis of the patient. Also, it is imperative to differentiate primary EMPD from a secondary type, in the latest the identification of the primary site of the tumor being vital for the patient.

REVIEW ARTICLE

Nonoperative management of high-grade splenic injury. A review of the literature and case report

Bogdan Socea[1], Cristiana Bogaciu[2], Alexandru C. Carâp[1], Vlad D. Băleanu[2], Dragoş V. Daviţoiu[1], Tiberiu Ş. Ţenea Cojan[3], Ion Păun[3], Vlad D. Constantin[1]

Abstract: *Splenic injuries causedby traumatic events are common in the emergency departments, mostly because the spleen is frequently affected in trauma. The lesions of the spleen can be diagnosed using a contrast enhanced computed tomography and based on the results, the injury of the spleen is graded. The management of the patient can be operative or nonoperative. The choice of treatment is decided by the hemodynamic stability of the patient.*

INTRODUCTION

Blunt abdominal trauma mostly due to sports activities is common in the emergency departments in Europe and 30% of the polytrauma patients have abdominal organs injuries [1]. The most frequently injured organ in blunt abdominal trauma is the spleen, which is involved in about 32% of abdominal injuries [2, 3].

The splenic injuries could be treated surgically or by a nonoperative management. In cases of hemodynamically stable patients, nonoperative management of the blunt splenic injuries is preferred and the recognition of the overwhelming post splenectomy infections also sustains the nonoperative management [2, 4].

The splenic injury in trauma is diagnosed based on computed tomography (CT) and it can also show other injuries associated with trauma [5]. The sensitivity of the CT examination in detecting splenic injuries has been reported to be as high as 95% [6].

On trauma patients should be performed FAST to find the evidence of intraabdominal hemorrhage. The patients with positive FAST and unstable hemodynamically, with or without cardiovascular associated disorders [7-9], are rushed to the operating room and the stable ones are planned for contrast-enhanced computed tomography [10].

Based on the CT results, various grading systems were introduced to help physicians to take the best decision regarding the management of the patient [6].

The best known and used splenic and hepatic grading system is the one established by the American Associationfor the Surgery of Trauma (AAST) [11] (Figure 1).

Vascular injuries in splenic trauma with active bleeding could be detected on a contrast-enhanced helical CT scan as perisplenic material extravasation [6, 12].

The selection of the treatment, operative or nonoperative, is difficult, but there are some factors such as hemodynamic status, age, grade of splenic injury, quantity of the

hemoperitoneum and associated injuries useful to decide the optimal standard of care for the trauma patient [11].

The rate of success in the nonoperative management of splenic injuries is very high in many published series, between 80-94% in the cases of adult trauma patients[2, 11].

There is some evidence that older patients might have a worse prognosis with nonoperative management than younger patients, and several series have reported thatpatients older than 55 years are less likely to have a successful nonoperativemanagement [11, 13, 14].

Other option of treatment in splenic lesions is the splenic artery embolization, which is classified as nonoperative treatment. Splenic artery embolization is used to reduce the incidence of reccurent bleeding, factor that would lead to hemodynamic instability [15-17]. Studies confirm a high rates of splenic salvage after the combined treatments such as splenic artery embolization and nonoperative management [3].

Table 1: The splenic organ in Jury Scaling System of the American Association for the Surgery of Trauma, 1994 revision

Grade*	Injury description	
I	Hematoma	Subcapsular, <10% surface area
	Laceration	Capsular tear, <1 cm parenchymal depth
II	Hematoma	Subcapsular, 10–50% surface area, <5 cm in diameter
	Laceration	1–3 cm parenchymal depth that does not involve a trabecular vessel
III	Hematoma	Subcapsular, >50% surface area or expanding; ruptured subcapsular or parenchymal hematoma; intraparenchymal hematoma >5 cm or expanding
	Laceration	>3 cm parenchymal depth or involving trabecular vessels
IV	Laceration	Laceration involving segmental or hilar vessels producing major devascularization (>25% of spleen)
	Laceration	Completely shattered spleen
V	Vascular	Hilar vascular injury that devascularizes spleen

**Advance one grade for multiple injuries up to grade III*

The operative treatment is preferred in all cases of instable hemodynamically patients with/without dyselectrolytemia [18, 19]. There are two surgical options that the operator can take after examining the injury: splenectomy or spleen preserving surgery [20, 21].

There are some types of spleen preserving surgery including spleen packing, partial splenectomy or splenorrhaphy [11].

Spleen packing is used in selected cases with isolated splenic injuries and stable patients.

If the patient is unstable with a grade IV or V spleen injury splenectomy should be performed. Another surgical technique that can be performed is the partial splenectomy and this is possible because of the segmental nature of the splenic blood supply [20].

One of the most dangerous complications that could appear after a splenectomy performed in trauma is OPSI (overwhelming postsplenectomy infection). OPSI is an emergent condition which at first may develop as a mild infection and then rapidly progress to sepsis [22, 23] that has a 50-70% risk of mortality with or without treatment [24-28].

Vaccination against S. pneumoniae, N. meningitidis, and HIB are recommended in addition to a yearly influenza vaccine to avoid OPSI, but the administration of these vaccines is recommended after the postoperative day 14 to increase the immune response in patients who have undergone splenectomy due to trauma [29-31].

MATERIAL AND METHOD

We highlight the key aspects of the nonoperative management of blunt trauma splenic injuries by doing a review of the literature.

We researched the PubMed and Cochrane datebases for studies involving nonoperative management of the splenic traumatic injuries. The studies we analyzed were published between 2017 and March 2019.

CASE REPORT

We present the case of a 25-year-old woman, who came into the emergency room after a motocycle accident. The clinical examination showed tenderness in the left upper quadrant and the right arm was painful, the patient was stable hemodynamically. An X-ray of the right arm showed fracture of the radius and cubitus that were immobilized in a cast [32].

Point of care abdominal ultrasound was performed and it suggested a splenic lesion – non-homogeneous echostructure and hypoechogenic areas (Figure 1), and free fluid in Morrison and Douglas pouches (Figure 2).

The blood tests revealed anemia (hemoglobin 9.30 g/dL) and leukocytosis (14.510/uL).

Contrast-enhanced CT scan of the abdomen and pelvis revealed a grade III splenic injury (5.6 cm hematoma and 2 cm laceration) (Figures 3, 5), fluid surrounding the liver, in the Morrison pouch, in the right and left paracolic gutters (Figure 6). No contrast extravasation at level of the spleen was detected, no other traumatic injuries (Figure 4).

Hypodense zones of splenic tissue should be differentiated from cystic lesions of spleen, even hydatid cyst that, in case of rupture, could mimic acute abdomen [33].

We decided to treat the patient conservatory, to monitor her clinically every 6 hours, the blood pressure and pulse were measured also every 6 hours and she was monitored ultrasonographic daily. There were no modifications during the admission into the hospital and the patient was discharged in the fifth day. She was informed about the signs of hemorrhage (abdominal pain, light-headedness, syncope, difficulty breathing and chest pain) and she was instructed to call immediately a surgical emergency center if any of these symptoms appear.

One week after the discharge the patient came to follow up, she was examined clinically, ultrasonographically and biologically and everything was normal.

At this moment, there is no information about the nonoperative management of the splenic trauma regarding how long should the patient be admitted, how long should it be between the discharge and the follow up, how frequently should the level of hemoglobin and hematocrit be measured and how frequent should the patient be examined ultrasonographically [34, 35].

CONCLUSION

Splenic injuries are common and the patients stable hemodynamically who have grade III splenic lesions due to trauma could be managed nonoperatively. There are no protocols about the nonoperative management of the splenic injuries and we think their existance could influence the morbidity and mortality of these patients. Prospective trials could be performed to establish a protocol of treatment and follow up.

Normal pressure hydrocephalus – Diagnosis and therapeutic challenges

Alin V. Chirtes[1], Teofil Mures[1], Marian Mitrică[1]

Abstract: *Normal pressure hydrocephalus (NPH) is a rare pathological condition that generally affects older people (>65 years old), and can take one of two forms: idiopathic or secondary. It is a reversible cause of dementia, and it manifests itself through a very specific triad: gait impairment, urinary incontinence, and dementia. The clinical diagnosis of NPH is particularly difficult to establish due to the association between these symptoms and old age, as well as due to the absence of specific paraclinical markers. Nevertheless, a holistic application of clinical, imagistic, paraclinical criteria, as well as of the various developed scales may, in time, lead to a diagnosis. Moreover, the evolution of magnetic resonance imaging has certainly made easier to establish the condition. The sole therapeutic method proven to be efficient is shunting surgery which has good results in the majority of the cases, showing clear signs of improvement from the very first-day post-surgery.*

Keywords: *normal pressure hydrocephalus, ventriculoperitoneal shunt, aqueductal stenosis, cerebral ventriculomegaly, communicating hydrocephalus, obstructive hydrocephalus*

INTRODUCTION

Normal pressure hydrocephalus (NPH) was firstly recognized by Adams et al. in 1965, by identifying a number of patients suffering from hydrocephalus, but having a normal pressure in the cerebrospinal fluid (CSF) at the lumbar puncture (LP) [1]. This represented a potentially reversible syndrome. The pathology is most often present in older people, and it manifests itself through a gait disturbance, urinary incontinence, and cognitive deficit. It has also been determined that gait impairment, along with one other characteristic element is essential for diagnosis. The clinical assessment demands further examinations, such as brain imagery or draining the CSF, to properly confirm the condition [2].

Traditionally, hydrocephalus was divided into two types: communicating hydrocephalus or obstructive hydrocephalus (non-communicating). The former type is characterized by an increase in the volume of CSF without any stenotic lesions in the drainage. In this case, the classification of NPH is still the one being used since 1965: idiopathic NPH (iNPH) – in roughly 50% of all cases, and secondary NPH (sNPH), which comes as a result of either subarachnoid hemorrhage (SAH), intracerebral hemorrhage (ICH), meningitis, intracranial tumors or trauma [1]. While iNPH is generally noticed at adults, sNPH may be present at any age, with both genders being affected equally [3]. Apart from the ventriculomegaly, there are no other observable radiological signs.

Obstructive or non-communicating hydrocephalus comes after the stenosis of the drainage between ventricles and the subarachnoid space, either congenital or acquired. The stenosis of the cerebral aqueduct is a common cause in young adults, although the symptoms are not visible until

[1] Department of Neurosurgery, Carol Davila University Central Emergency Military Hospital, Bucharest, Romania

adulthood [4].

In the largest study ever conducted on NPH, in Sweden, the results estimated a 0.2% prevalence in the 70-79 age group, and 5.9% in those aged over 80 [5]. In Japan, the results estimated a 0.01% prevalence in the general population and 0.03% in those aged over 60 [6]. In another study on a Finnish cohort, the incidence was 1.58 for every 100.000 persons [7].

The comorbidities associated with NPH are: Alzheimer disease (15%), chronic high blood pressure (50%), hyperlipidemia (14%), and diabetes mellitus (20%) [6, 7]. The latter two factors increase the risk of developing NPH by doubling it, as compared to a normal patient [8]. Similarly, obesity and psychological stress, heart diseases, and strokes have also been named as contributory to the development of this pathology [8, 9].

Unfortunately, the criteria for NPH diagnosis remain uncertain. While some specialists consider it the most common form of hydrocephalus in adults, others contest its very existence [3, 10, 11].

NPH is difficult to diagnose due to its broad and general symptomology, commonly associated with old age. Thus, in individuals aged over 75, urinary incontinence is present in 20 to 30% of them, whereas 20% develop some kind of dementia and 20% show signs of ventriculomegaly [4]. Implicitly, the management of NPH is equally difficult, due to the complications associated with shunting. As such, the morbidity and mortality rates are 20% and 0.2%, respectively [12].

PHYSIOPATHOLOGY

The CSF is mainly secreted by the cells of the choroid plexus, other regions playing mainly a rather insignificant role. CSF's volume is between 125 and 150 ml, and its secretion varies between 400 and 600 ml daily, renewing itself 4 to 5 times every 24 hours in a healthy adult [13]. Its role is vital, namely, the protection and nutrition of the parenchyma [14]. Furthermore, its dynamic is highly dependent on the rate of production and absorption, as well as on the blood-related pulsatile flow through both the subarachnoid and Virchow-Robin spaces to the cerebral parenchyma [15, 16]. According to Adams et al. original theory, NPH develops when the level of CSF's reabsorption diminishes, thus resulting in intracranial hypertension, leading to ventricular dilation as a compensating mechanism [1]. Hence, a larger volume of CSF is redirected to the Virchow-Robin spaces, giving birth to a compression of the parenchyma and ischemia of the white matter.

The specific pathophysiology of iNPH is unclear, yet various mechanisms have been put forward as possibly involved in developing the pathology, such as [2]:

- Reduced compliance of the subarachnoid space
- Reduced reabsorption of CSF in the venous system
- Inadequate expression of TNF-alpha in CSF
- The hyperdynamic flux of CSF in the cerebral aqueduct
- The higher pressure of the CSF
- The reabsorption of CSF through abnormal mechanisms

CLINICAL PRESENTATION

iNPH must be suspected in older patients suffering from abnormal walking, sometimes combined with dementia or urinary incontinence [3].

Symptomatology can vary massively between patients. They may show signs with the classic triad in percentages of 30 to 50 (gait disturbance, urinary incontinence, and cognitive deficit), or only a combination of these: only gait impairment (5%), only dementia (2%), both combined (28%), gait abnormality together with urinary incontinence (4%) and dementia accompanied by urinary incontinence (1%) [6][17]. Approximately half of the patients with iNPH only show signs of a gait disorder, the other two characteristic symptoms being absent [6].

DIAGNOSIS

According to international guides, the imagistic diagnosis is based on the following elements [18]:

- Ventricular dilation with an Evans index > 0.3 [19]
- The absence of a macroscopic obstruction of the dynamics of the CSF
- At least one of the following [20]:
    - o Callosal angle exceeding 40° [21]
    - o Temporary dilated temporal horns of the lateral ventricles, but not fully due to the atrophy of the hippocampus
    - o Changes in the CT and MRI signal caused by the alteration of the content of cerebral water, not fully owed to the microvascular ischemic modifications or demyelination.
    - o Signs of a "flow void" in the MRI in the Sylvian aqueduct

The following imagistic methods can be engaged as well: MR elastography (MRE), glymphatic MRI, or the Silver index [22, 23, 24].

Regarding the Evans index, it is established based on a CT scan in the axial incidence. An index exceeding 0.3 indicates a pathological condition of the ventricles (sensibility of 80%) [19]. The threshold for indicating a pathological component varies by age, namely: between 65 and 69 years – 0.34; between 70 and 74 years – 0.36; between 75 and 79 years – 0.37; between 80 and 84 years – 0.37 [19].

Callosal angles are measured based on a CT or MRI scan, at the median point of the corpus callosum [21]. Identifying this point necessitates using the sagittal plane, placed parallel to the floor of the fourth ventricle [21]. The limit was 105.4° (42% sensibility, 87% specificity) [21]. It is deemed that, with the decrease of every degree in callosal angles, a patient has a 4% greater chance of benefitting from a shunting surgery [21].

The Japanese guidelines for diagnosing NPH do not regard periventricular changes as relevant. However, they do include two new criteria of diagnosis, i.e. Sylvian fissures and enlarged basal cisterns, as well as the narrowing down of the subarachnoid space and the cerebral sulci at the median level of the brain [25]. In 2017, the efficiency of the two guides was debated, since there are significant discrepancies from the international medical practice, the former being substantially more specific, demanding the presence of at least two symptoms of the classic triad to confidently identify the diagnosis [26]. Furthermore, the study has underlined the necessity of a common system for diagnosis, more objective than the current one [26].

Clinically, several procedures could be executed to diagnose NPH. Firstly, "tap test" or CSF's evacuation test consists in removing 30-50 mL of CSF through a lumbar puncture, to improve the symptomology, the association of the gait function with the frontal assessment battery score, the improvement of verbal fluency and gait [25, 27, 28, 29]. Secondly, different weights can be given to the various markers from CSF, such as the expression of certain isoforms of transferrin, of the tyrosine phosphatase Q-type receptor, or has-miR-4274. Similarly, the correlation between slow vasogenic waves (SWV) and intracranial pressure must be investigated [30].

DIFFERENTIAL DIAGNOSIS

The differential diagnosis must be performed with Alzheimer disease (AD), frontotemporal dementia, dementia with Lewy body, the one from Parkinson disease (PD), the one associated with AIDS, dementia caused through corticobasal degeneration and any other type.

Generally, the level of proteins in the CSF is measured, considered alongside biomarkers of the AD. In this particular case, the level of p-tau and t-tau are high, whereas the level of a β-amyloid peptide (Aβ) is low [4]. In the particular case of NPH, all these parameters are high, going back to normal values after shunting [31].

Apart from the AD, the PD, as well as other parkinsonian syndromes cause gait impairment [4]. Numerous investigations can be carried out, such as SPECT (Single Photon Emission Computed Tomography), this being limited through detecting an exhaustive set of neurodegenerative diseases, or FDG-PET (Fluorodeoxyglucose – Positron Emission Tomography), which can identify caudate hypometabolism, a potential marker of NPH [4].

TREATMENT

The clinical presentation of NPH is insufficient to recommend ventriculoperitoneal shunting surgery (VPS), because either one of the symptoms of NPH may have multiple potential etiologies. The diagnosis must be established clearly through the abovementioned methods in order to recommend surgical treatment.

VPS is the only efficient method of treatment for iNPH, by implanting a ventriculoperitoneal shunt. The international and Japanese guides, as well as AAN (American Academy of Neurology), confirm VPS as the only efficient method of treating iNPH, as opposed to the rather supposedly inefficient endoscopic approach of the third ventricle [25, 32, 33].

The purpose of a shunt is to drain CSF towards space where it may be reabsorbed. A shunt has three components: a proximal catheter, inserted at the level of the right lateral ventricle, a distal catheter in the peritoneal cavity, and a valve of shunting which contains a mechanism opening the valve up when the difference in pressure between the two cavities reaches a pre-established value [3]. Once the valve is open, CSF is drained in the peritoneum. Another approach is represented by lumboperitoneal shunt (LPS), which has the proximal end in the lumbar zone. In a study from Japan, it has been stated that LPS is used in 55% of the cases, whereas VPS is used in 43% of the surgical cases of NPH [6]. Another option of VPS is placing the distal end of the shunt between the two sheets of the greater omentum, the technique is considered as having good results and a low rate of post-surgery complications [34].

Concerning the efficiency of the shunting surgical treatment, in the first three months, in most cases, the headache is gone, and the gait deficit has improved in 85% of the cases, urinary incontinence in 70%, and cognitive functions in 65% [35].

In a study on the efficiency of LPS, it has been concluded that the method is comparable with VPS for patients showing signs of NPH. Nevertheless, the revision of the shunt took place more frequently in patients with LPS than in those with VPS [36].

Regarding the prognostic, 60% of the patients have benefitted from an improvement in symptomatology after the shunting surgery, and 40% have shown signs of significant improvement. These were measured using the mRS scale [9]. Both pre-surgery and post-surgery, patients must be evaluated using the following systems: Japanese NPH scale, Berg scale, DGI (Dynamic Gait Index), FIM (Functional Independence Measure), MMSE (Mini-Mental Status Examination), and TUG (Timed Up and Go) [2].

A series of post-surgery factors can suggest a good prognostic, such as: an aqueduct flux exceeding 42 µl, the absence of lesions of the white matter on MRI, resistance to the CSF debit exceeding 18 mmHg [2]. Antagonistic factors are severe dementia, dementia as a symptom of presentation and MRI abnormalities such as cerebral atrophy or lesions of the white matter [2].

Complications that may arise include:

- Surgical complications of the shunt: the failure of the shunt (3%), under- or over-drainage, subdural hematoma (3-4%), infections (1%) [37];
- Surgical complications unrelated to the shunt: seizures and intracerebral hemorrhage (under 5%) [2];
- Schizophrenia – 3 to 4 times more likely in patients with iNPH than in the healthy population [38];
- Hypertension and diabetes type 2 are frequent in iNPH patients, the latter risk factor causing increased mortality in affected patients [7].

CONCLUSIONS

NPH is a rare, yet treatable disease, and the diagnosis may be difficult to establish due to the rather broad symptoms. Both iNPH and sNPH cause similar features.

The difference between the idiopathic and secondary hydrocephalus has led to a difference in approach in a similar pathology, the latter being labeled as a surgical emergency. Both the concept of NPH, as well as the therapeutic approach retain a status of controversy. The diagnosis of iNPH must be considered when a patient shows signs either of the classic triad, or of some elements of it, or in the case of suggestive imagistic criteria.

Following this evaluation, treatment must be sought only when the risks and benefits of the shunt are carefully balanced. Recent innovations in the field of imaging have greatly improved the identification of patients who may benefit from shunting surgery. Furthermore, it should be also keep in mind that patients suffering from iNPH also present associated comorbidities, such as PD, AD, or other neurodegenerative diseases. Hence, the diagnosis must include tests that draw a clear distinction between NPH and these potentially present diseases. For the same reason, the patient's response to the drainage of CSF can be unpredictable.

NPH must be seen as a reversible cause of dementia. In the future, ample studies must be made to demonstrate the efficiency of shunting surgery.

Abstract: Cardiac amyloidosis (CA) represents the accumulation and deposition of misfolded protein fibrils in the myocardium, resulting in progressive restrictive cardiomyopathy. Light chain (AL) and transthyretin (TTR) amyloidosis are the most common types of CA. While endomyocardial biopsy remains the gold standard for diagnosing cardiac amyloidosis, its invasive nature and associated risk of complications have led to increased reliance on clinical suspicion and noninvasive imaging modalities as alternative diagnostic tools. Over the last decade, radionuclide imaging studies have become a widely accepted tool in diagnosing ATTR CA, whereas its diagnostic utility in AL CA detection remains limited. Recent advances in PET-CT radiopharmaceuticals have further expanded the potential of nuclear imaging as a comprehensive tool for diagnosis, prognostication, and therapy monitoring. This literature review appraises the current applications of nuclear imaging in the clinical management of cardiac amyloidosis.

Keywords: Cardiac amyloidosis; Transthyretin amyloidosis; Light-chain amyloidosis; Radiolabeled bisphosphonates imaging; Amyloid-specific PET tracers; Non-invasive cardiac imaging

INTRODUCTION

Amyloidosis is a heterogeneous systemic disease characterized by the aggregation and extracellular deposition of misfolded protein fibrils in various tissues and organs [1]. The term ‘amyloid’, derived from the Greek άmylon and Latin amylum – both meaning ‘starch’, in reference to its iodine staining properties – was first introduced into the scientific literature in the 19th century to describe iodine-positive deposits observed in the brains of patients with dementia [2]. Cardiac amyloidosis (CA) refers to myocardial infiltration by amyloid fibrils, leading to progressive restrictive cardiomyopathy and associated cardiovascular manifestations. Although the type of CA cannot be differentiated based on patterns of deposition, there seems to be a prevalence of diffuse, pericellular, endocardial, and arterial or arteriolar deposits in AL amyloidosis, with nodular deposits in TTR amyloidosis [3].

The most frequent clinical forms – accounting for more than 95% of cases – are light-chain (AL) and transthyretin (TTR) amyloidosis [3]. AL (or primary) amyloidosis results from the deposition of misfolded immunoglobulin light chains, aggregated as amyloid fibril precursors. These last can damage the tissues directly – through their

proteotoxicity – or form stable fibrils – causing organ damage through impaired histological architecture [2]. TTR amyloidosis is characterized by pathological deposits of transthyretin, a normally occurring protein used in transportation of thyroid hormones and retinol-binding [4]. Wild-type transthyretin amyloidosis (ATTRwt) – formerly known as senile systemic amyloidosis – is an age-related form of cardiac amyloidosis, most often presenting in the seventh decade of life, with a marked male predominance [2,5]. In contrast, variant transthyretin amyloidosis (ATTRv), which is inherited in a dominant autonomic fashion with incomplete dominance, may present as early as the third decade of life, depending on the specific mutation [2,3,5].

With divergent prognoses, treatment strategies, and therapeutic responses, early and precise diagnosis of the distinct forms of cardiac amyloidosis is therefore essential to guide appropriate and timely management. While endomyocardial biopsy remains the gold standard for diagnosing cardiac amyloidosis, its invasive nature and associated risk of complications have led to increased reliance on clinical suspicion and noninvasive imaging modalities as alternative diagnostic tools [4,6].

This paper aims to present current nuclear imaging modalities of diagnosing cardiac amyloidosis and to synthesize recent evidence regarding their prognostic significance and role in evaluating therapeutic response in patients with CA.

CLINICAL SPECTRUM, BIOMARKERS, AND CONVENTIONAL IMAGING

Clinical manifestations

Cardiac amyloidosis is associated with a spectrum of clinical manifestations reflecting the gradual myocardial infiltration and consequent restrictive physiology. Amyloid infiltration leads to progressive thickening of the atrial and ventricular walls, culminating in diastolic dysfunction and heart failure (HF) – often with preserved ejection fraction. Systolic dysfunction typically occurs in the later stages of the disease. While atrioventricular block and tachyarrhythmias also become increasingly clinically apparent as the disease advances, common cardiac symptoms include fatigue, shortness of breath, and syncope [2,3].

AL amyloidosis, caused by clonal plasma cell dyscrasias, typically presents as a multisystemic disease, most frequently involving the heart and kidneys (60-70%), but also the liver (15%) and peripheral nerves (10%) [3]. The amyloidotic heart shows symmetrical increase in biventricular wall thickness (pseudohypertrophy) with markedly increase LV stiffness and filling pressures – in the presence of nondilated or small ventricles [2]. Due to restrictive cardiomyopathy and fibril proteotoxicity, patients with AL amyloidosis can present with dyspnea, fatigue, arrhythmias, severe fluid retention, hepatomegaly and ascites [1,2]. Circulating light chains exert direct cardiotoxic effects, contributing to rapid disease progression and disproportionately elevated cardiac biomarkers relative to amyloid burden [3]. Late-stage diagnosis, when cardiac and renal damage is advanced, correlates with a poor survival – measured in weeks [1,3].

ATTR amyloidosis also presents with a cardiac-dominant phenotype – manifesting as left ventricular hypertrophy (LVH) and HF [5] – particularly in the wild-type form (ATTRwt), which affects elderly men and follows a slow progression. Early extracardiac manifestations, such as bilateral carpal tunnel syndrome, lumbar stenosis or biceps tendon rupture, may precede cardiac symptoms by several years [1,3]. Severe aortic stenosis (SA) has been associated with cardiac amyloidosis, especially in the ATTR variant, as amyloid fibril deposition within valvular tissue contributes to leaflet thickening and progressive stenosis. The coexistence of CA and SA has been reported to have a poorer prognosis; therefore, concomitant diagnosis is essential in guiding appropriate therapeutic management [7]. ATTRv manifestations vary by mutation: Val122Ile leads to predominant cardiac involvement, while Val30Met causes early-onset neuropathy and Thr60Ala produces mixed features [3]. Late-onset ATTRv and ATTRwt share similar cardiac presentations and fibril compositions, often involving both full-length and fragmented transthyretin [2].

Serum biomarkers

When cardiac amyloidosis is suspected, initial evaluation should include serum measurements of N-terminal pro-B-type natriuretic peptide (NT-proBNP), troponin, creatinine and free light chains, along with calculation of estimated glomerular filtration rate (eGFR). A study by Ionescu et al. [8] found the burden of cardiac amyloidosis on eGFR to be more pronounced in ATTR patients compared to AL, regardless of the method used (either by MDRD formula or the Cockcroft-Gault equation).

Assessment of serum and urinary free light chains should be performed to aid the differentiation between ATTR and AL amyloidosis. An abnormal kappa-to-lambda free light chain ratio may be indicative of AL amyloidosis. For further evaluation of the differential diagnosis, bone marrow biopsy is recommended to distinguish between AL amyloidosis and multiple myeloma [2].

Electrocardiography

As one of the simplest yet highly informative diagnostic tools, electrocardiography (ECG) can reveal several 'red flags' – particularly when interpreted in conjunction with imaging findings – allowing for a refined prognosis and stratification. ECG appearances suggestive of cardiac amyloidosis are defined by a pseudoinfarction pattern and disparity between the LV wall thickness and low QRS voltage. Due to myocardial infiltration of non-conductive material, the direct proportionality correlation between QRS voltages and LV mass is therefore abolished. The pseudoinfarction pattern consists of the presence of Q waves measuring at least 1mV in at least 2 contiguous leads, in the absence of ischemic heart disease and/or regional kinetic abnormalities of the LV [2,5]. In AL CA, low peripheral voltage is more common due to proteotoxicity of misfolded light chains, whereas ATTR CA presents more frequently with conduction disease (incomplete or complete bundle branch block), arrhythmias (atrial flutter or fibrillation) and bradycardia [2,3].

Echocardiography

Echocardiography signs suggestive for cardiac amyloidosis consist of increased LV wall thickness (>12 mm) with relative apical sparing ("cherry on top"), low tissue doppler velocities, restrictive filling pattern, increased biatrial volume, atrial septal thickening (>6 mm) and pericardial effusion. LV wall thickness is usually more pronounced in ATTR CA (>15 mm), which also presents more commonly with concomitant aortic stenosis [3,9]. Combining ECG and echocardiographic findings has been shown to provide higher diagnostic accuracy, with 91% sensitivity and 89% specificity in cases with a ratio<0.4 between R-wave amplitude in lead I and posterior wall thickness [2].

Cardiac magnetic resonance (CMR)

Cardiac magnetic resonance imaging, particularly late gadolinium enhancement (LGE) and T1 mapping techniques, allows for noninvasive tissue characterization, therefore aiding the differential diagnosis of cardiomyopathies with hypertrophic phenotypes by detecting amyloid deposits in the myocardium [9]. Morphofunctional quantification reveals concentric and symmetric left ventricular hypertrophy with preserved ejection fraction but reduced indexed stroke volume – often in the context of diastolic dysfunction. Associated findings include thickened valves, left atrial appendage thrombi, atrial enlargement, interatrial septum hypertrophy and mild pericardial and pleural effusions. Increased native T1 mapping is particularly sensitive for early myocardial involvement, often detecting abnormalities before late LGE becomes apparent. Especially during early to intermediate contrast phases, LGE typically demonstrates diffuse subendocardial enhancement in a non-coronary distribution with relative apical sparing. In advanced stages of CA, transmural or intramyocardial, patchy enhancement may be observed, extending into the right ventricle or atria. Characteristic features include myocardial nulling preceding blood pool nulling and early blood pool darkening. Additionally, elevated extracellular volume (commonly>40%) serves as an indirect marker of amyloid burden and correlates with disease severity and prognosis [2,10].

NUCLEAR MEDICINE IMAGING IN CARDIAC AMYLOIDOSIS

Radiopharmaceuticals

Non-amyloid specific radiopharmaceuticals currently used in cardiac scintigraphy are bone-avid radiotracers. These radiopharmaceuticals are labelled with 99mTechnetium: 99mTc-diphosphono-1,2-propanodicarboxylic acid ([99mTc]Tc-DPD), 99mTc-pyrophosphate ([99mTc]Tc-PYP) or 99mTc-hydroxymethylene diphosphonate ([99mTc]Tc-HMDP) [11]. A comprehensive study by Gilmore et al. [12] has shown high specificity and sensitivity of 99mTc radiotracers for TTR amyloidosis, which correlates with negative monoclonal proteins in blood and/or urine samples. It is not yet fully understood why phosphonate compounds accumulate in cardiac tissue at the sites of amyloid deposition. It is hypothesised that this is because amyloid fibril deposits have a higher concentration of microcalcifications in the cardiac TTR, together with slow disease progression and therefore the potential for greater accumulation of deposits in the myocardium and/or other systemic structures. [4,13,14]

A study conducted by Park et al. [15] comparing 99mTc-PYP and 99mTc-DPD showed that the latter may be more useful in evaluating the severity of the disease. They found a more significant relationship between uptake and visual grading, as well as with biological parameters in [99mTc]Tc-DPD scans. Further studies are necessary in order to formulate a proper conclusion.

Quarta et al. [16], in their study of [99mTc]Tc-DPD uptake in AL CA, found a high percentage of patients with bone tracer uptake, almost a third of them with moderate cardiac uptake. This emphasizes the necessity of serological exclusion of plasma cell dyscrasia in case of bone tracer uptake in the myocardial tissue.

There has been a growing interest in recent years for the applicability of amyloid specific radiotracers, used in positron emission tomography – computed tomography (PET/PET-CT) studies in the diagnosis of cardiac amyloidosis [17]. Their primary use is for detection of Alzheimer disease [18]. These radiotracers bind directly to the beta amyloid, thus identifying any other systemic sites of amyloid aggregates. They are not yet approved for clinical use in diagnosis of CA but have shown promising results [19]. Rosengren et al. [20] were able to show high accuracy of 11C-labeled Pittsburgh compound B ([11C]PiB) in the detection of AL CA. Patients with documented systemic amyloidosis and only cardiac wall thickness also had [11C]PiB uptake on PET-CT scans, suggesting a prospective use of it in preliminary stages of the disease. Furthermore, Choi et al. [21] showed that PET-CT with [11C]PiB is a reliable independent factor for 1 year survival in patients with AL CA, alongside other established bio-indicators. The survival rate after 1 year in their 35 patients with [11C]PiB uptake was a little over 50%. Lee et al. [22] determined that PET scans with [11C]PiB are useful in quantifying the degree of amyloid burden by grade of uptake. Their prospective study reflected the usefulness of [11C]PiB in predicting overall outcome. A reduction in the uptake after treatment was observed in a small number of patients, raising the possibility of [11C]PiB PET as a non-invasive tool of assessing treatment response.

Similarly, Genovesi et al. [23] tested the feasibility of [18F]Florbetaben PET-CT for detection of AL amyloidosis. Their results showed that it may be able to detect light chain amyloid burden and to discriminate between forms of CA and other restrictive cardiomyopathies. Along with a previous pilot study by Law et al. [24], both may endorse the use of [18F]Florbetaben as a non-invasive imaging technique to diagnose AL amyloidosis, yet further studies are necessary. It may represent an aid to scintigraphy, which cannot discriminate from other than TTR cardiac amyloidosis.

Apart from the amyloid-specific radiotracers, Wang et al. [25] showed the potential use of 68Ga-labeled Fibroblast Activation Protein Inhibitor ([68Ga]FAPI) PET-CT imaging for the diagnosis of AL CA, due to fibroblastic activity – a possible new instrument in heart failure and its cardiac implications [26].

Radionuclide imaging techniques

Planar acquisition

Interpretation of the cardiac planar images is based on a relatively simple visual scoring and a semiquantitative analysis. The visual grade consists of the Perugini score (Table 1), comparing the intensity of the cardiac uptake with rib cage uptake, and is more useful in case of [99mTc]Tc-DPD or [99mTc]Tc-HMDP [13, 27]. Grade 0 represents no cardiac uptake of the 99mTc radiotracer – and normal uptake of the ribs – being considered negative for CA. Grade 1 – equivocal for the diagnosis of ATTR amyloidosis – consists of mild cardiac uptake, less than rib uptake. Grade 2 represents cardiac uptake of the radiotracers equal to the rib uptake, while Grade 3 translates to a cardiac uptake greater than that of the rib cage. Grades 2 and 3 on planar studies are considered ATTR positive – after the exclusion of plasmatic dyscrasia [28].

Table 1: Visual grading system of myocardial radiotracer uptake on bone scintigraphy according to the Perugini score

Perugini score	Cardiac uptake
Grade 0	absent
Grade 1	cardiac uptake < rib uptake
Grade 2	cardiac uptake = rib uptake
Grade 3	cardiac uptake > rib uptake

Semiquantitative indicators consist of several methods of evaluation, including the heart-to-contralateral ratio (H/CL), most valuable in the case of bone scintigraphy with [99mTc]Tc-PYP [13]. The H/CL measures the ratio between the counts in the two regions of interest (ROI) – the heart and the contralateral lung. With a value greater than 1.5 on one-hour acquisitions, in correlation with a Perugini score of 2 or 3, the cardiac study is highly suggestive of TTR cardiac amyloidosis [28]. However, in cases where the Perugini score is classified as grade 1, histological confirmation of amyloid deposits (potentially located in the extracardiac tissues) is required to establish the diagnosis and determine the amyloid type [29].

The current standard time between injection and acquisition is between one (1h) and three hours (3h) [30]. Images at one hour have a higher sensitivity due to peak myocardial uptake, yet it is of higher specificity in the case of delayed images [17]. Saitou et al. [31] confirmed this remark by a comparison between planar acquisitions at 1h and 3h post-injection on radiolabeled bisphosphonate scans with [99mTc]Tc-PYP. Their study showed a higher specificity in planar 3h studies – results corroborated with single photon emission computed tomography with computed tomography (SPECT-CT). Moreover, a 3h scan can provide a more accurate diagnosis, as proven by their differences in positive predictive values (almost 80% after 3h versus 57% after 1h). Similarly, Nichols et al. [32] emphasized the advantages of using 3h planar and SPECT-CT images for diagnosis. Three-hour acquisitions are advantageous due to lesser blood pool activity and peak bone uptake [11].

SPECT and SPECT-CT

SPECT-CT, a hybrid imaging technique that evaluates function through SPECT and anatomy through CT, provides a useful three-dimensional assessment with the possibility of segmental evaluation and attenuation correction [13].

The visual scoring on planar images is a well-established and reliable method of analysis. Nevertheless, it is prone to misinterpretation because of blood pool activity, osseous uptake that overlaps the cardiac region or inexperience of the interpreter [30]. SPECT-CT images are able to confirm the diffuse left ventricular, biventricular, interventricular septum and/or atrial myocardial uptake of the radiotracers, highly suggestive of cardiac amyloidosis.

Quantification of cardiac uptake on SPECT-CT using standardized uptake values (SUV) was shown to have greater accuracy than visual assessment on planar-only acquisitions. SUV is a semiquantitative index that reflects the uptake of radiotracer in the tissue, but it has yet to be included in standard practice. It is the ratio between radioactivity in a region of interest (ROI) and the dose administered per the body weight of the patient. Kessler et al. [33] compared quantitative SPECT and SPECT-CT results with those obtained through Perugini score in suspected CA patients that underwent [99mTc]Tc-DPD scintigraphy. A value of SUVmax greater than 6.1 showed a higher specificity for CA and particularly for ATTR type – where a 99% specificity value has been reported. Furthermore, in a study by Taha et al. [34], the use of SPECT-CT fusion was able to enhance diagnostic accuracy by adding the anatomical element of the low-dose CT in order to differentiate between myocardial and ventricular diffuse uptake (blood pool uptake). Scully et al. [35] showed that the use of SPECT-CT and SUV values offers a more accurate means of distinguishing between Perugini scores of 2 and 3.

PET-CT

PET-CT imaging can be a more precise tool in describing anatomical and functional characteristics of the disease. PET-CT scans offer more accurate quantifying methods of the biological and physiological processes through SUV values, retention index, target-to-background ratio, as well as visual grading [30]. Amyloid-binding PET radiotracers have accumulated a substantial amount of evidence; however, they are not yet licensed for clinical application in CA. Further investigations are needed to optimize acquisition procedures and validate results in broader groups. In contrast to bone-avid scintigraphy and SPECT radiotracers, PET radiopharmaceuticals have been explicitly designed to attach to the amyloid fibrils. Consequently, PET is the sole imaging modality that is unequivocally selective for amyloid deposits and highly selective for amyloid variants. Moreover, PET is capable of detecting ATTR CA, AL CA, as well as uncommon hereditary variants. Advancements in the quantification of myocardial uptake in both SPECT and PET have produced more detailed and consistent results, facilitating improvements in early diagnosis, risk stratification, and treatment response assessment [36].

DISCUSSION AND FUTURE PERSPECTIVES

Atrial and right ventricular uptake: a new perspective in radionuclide cardiac imaging

The diagnostic role of scintigraphy with bone-avid radiotracers in the diagnosis of CA – specifically of TTR form – is almost in all cases unequivocal [12,37]. However, their role in the prognosis of CA remains still unclear. Recent years' studies have focused on this perspective.

The amyloid burden can be easily identified in the left ventricle alone – yet in most cases, biventricular and/or atrial strain is present, leading to restrictive myopathy [3]. Two promising fields of research regarding the role of radionuclides in prevention and prognosis assessment are the increased uptake in the atrium and in the left ventricle on scintigraphy. Porcari et al. [38] studied the implications of right ventricular uptake of bone radiotracers on scintigraphy. Their results showed a biventricular uptake in 100% of their total of 1422 patients with TTR amyloidosis, identified on SPECT and inconsistently on planar “whole-body” images. It is known that right ventricle involvement in heart failure is linked to an unfavorable disease evolution [5]. This study [38] identified a diffuse right ventricle uptake in more than half of their patients, which was an independent mortality predictor.

Atrial involvement is a part of the onset of cardiac alterations [37]. It appears as part of global amyloidosis (AL or TTR) or as regional impairment of the atrial function due to pathological natriuretic peptide accumulation age related [39]. Hussain et al. [40] reported a high percentage of patients with TTR amyloidosis and atrial fibrillation (AF) to have atrial uptake on [99mTc]Tc-PYP planar images and SPECT-CT. Scintigraphy with 99mTc derivatives is unequivocally useful in assessing the ventricular uptake. Nonetheless, this study raised awareness for atrial implications – with or independent of that of ventricular – related to prevalent high-risk cardiovascular manifestations (AF, thrombi, pulmonary embolism).

National and International Guidelines

Adopting a uniform, standardized protocol, locally and internationally, for nuclear medicine studies for CA, would ensure the best accuracy of disease detection, thus improving the therapeutic approach and prognosis of the patient.

A recent study done by Stan et al. [41] showed the necessity of implementing national standardized protocols – including acquisition times and interpretation algorithms – for accurate reporting of CA scintigraphy studies.

CONCLUSION

As of today, nuclear medicine imaging studies represent a viable and reliable non-invasive imagistic method to diagnose cardiac amyloidosis. Furthermore, what was once an incurable disease with scarcely any treatment prospects is now more easily and promptly diagnosed with the courtesy of vast improvements in the field of radiopharmaceuticals used in cardiac nuclear imaging. While the diagnostic value of bone-avid radionuclides is unequivocal in TTR cardiac amyloidosis, novel indicators of their use in earlier stages or cardiac particularities (atrial or right ventricle uptake associated with unfavorable outcomes) are highlighted through recent studies, persuading specialists to study more this field. Furthermore, with promising results in cardiac imaging, PET may be considered and approved as a viable means of diagnosis, assessment of prognosis, and response to therapy.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration for publication elsewhere. This research received no external funding.

Authors' contribution

Conceptualization G.S.P.,M.M.M. and S.M.S..; methodology, G.S.P., L.E.M., M.G.; validation, D.M. and S.M.S.; data curation, D.M., G.S.P., M.M.M.; writing—original draft preparation, G.S.P, M.M.M, B.C.; writing—review and editing, L.E.M.,C.M., V.C.M..; supervision, S.M.S.; project administration, S.M.S..; All authors have read and agreed to the published version of the manuscript.

Ethics approval and consent to participate

The study was conducted under the Declaration of Helsinki. The research was conducted under ethical guidelines and regulations, ensuring compliance with all necessary protocols.

Patient consent for publication

Abstract: Acupuncture is one of the main components of Traditional Chinese Medicine and has been applied as a therapeutical method for centuries. As a therapeutical system, it is based on the use of specific lines in the human body, called meridians, and specific acupuncture points, for choosing the locations where the needles will be applied, depending on the specific problem. In the last few decades, there have been increasing efforts to detect and document the existence of such meridians and points based on at least some of their electrical properties being different when compared to the surrounding skin. A number of researchers have designed experiments, which have had varying degrees of success. Since different researchers have used different experimental setups, and the sample size is usually low, there are issues of validity and comparison between different research results. On the other hand, the majority of available evidence is in favor of there being points and lines characterised by distinct electrical properties, corresponding to acupuncture points and meridians respectively. At the same time, several other theories have been proposed to explain the biological basis of acupuncture points and meridians, while their connection to specific cellular components or neural sequences is an intriguing possibility. While comprehensive research is required to fully document the electrical properties of acupuncture points and meridians, a connection between such properties and their biological basis must also be established.

Keywords: acupuncture points; meridians; electrical properties; TCM; impedance; resistances

INTRODUCTION

Acupuncture is an integrative part of Traditional Chinese Medicine, and has been practised in China [1] and Japan and also in Korea [2, 3] for centuries. It is certain that acupuncture appeared in China although it is difficult to trace its exact historical era of emergence [4]; much later it would be disseminated in Japan, during the 5th century AD [5]. The practises of acupuncture would later become known to Europe by the end of the 17th century, through the works of Willem Ten Rhijne and Engelbert Kaempfer [6]. Following a hiatus of almost a century, after 1850, it would be again be advocated fervently by George Soulié de Morant in 1940s France, and gradually spread to Europe [7].

In the West, there is an ongoing disagreement regarding the efficacy of acupuncture in particular and of alternative therapies in general, both within and outside of the medical community, despite there being numerous studies which are in favour of acupuncture’s effectiveness [8-16]; iatrogenic complications and side-effects are also very rare [17]. Even veterinary acupuncture has been gaining traction as of late [18-21], although we will not be dealing with that in the present article; notably, research on acupuncture points has already began in earnest since the 1990s [22,

23] – there have even been some reports of the effects of acupuncture in plants [24-29]. It has long been accepted by numerous physicians and researchers that acupuncture can be integrated with modern Western medicine [11,30].

In contrast to the methods of Western medicine, also known as “evidence-based medicine”, the exact definition of acupuncture points and meridians and the associated “flow of qi”, which constitute the principal theory behind acupuncture therapy, is a concept that cannot be quantified and determined accurately by available technical means, at least for now. There are numerous research efforts which have attempted to describe the different electrical properties of acupuncture points.

The different electrical properties of acupuncture points compared to non-acupuncture points in the human body form the basis for the development of special acupuncture point locators, both for somatic and for auricular acupuncture points. It is important to note here that the existence of differences, at some physiological level, between random points and acupuncture points, lends credence to acupuncture being a legitimate therapeutic method more so than mere psychological suggestion [31] or some type of a placebo effect. A research by Vickland et al. [32] suggested that acupuncture changes the electrical properties of the acupuncture points themselves. Even so, the general difficulty in obtaining consistent and reproducible readings in certain points in the skin and the absence of any known physiological mechanism does not allow for a definite determination of the electrical characteristics of acupuncture points [33]. Recently, the advances in machine learning and artificial intelligence [34-39] may allow for different approaches and yield more conclusive results, although nothing definitive is available as of yet. It is possible that a part of the difficulties in establishing a clear-cut model for detecting TCM meridians and acupuncture points has to do with the biological structure of the skin.

The human skin comprises four successive layers, from the exterior to the interior: stratum corneum, living epidermis, dermis, and hypodermis. Detailed investigations into the structure and specific properties of the skin have been made by a number of authors [40-42]. Each of these layers has different conductive, capacitive and dielectric properties; predominantly these depend on the applied voltage although both age [43] and the relative health condition affect them [44]. In essence, parameters such as resistance, impedance and capacitance are a reflexion of the physical properties of the skin [45].

There exist a number of studies, detailing the different skin dielectric properties, depending on the applied voltage, at different frequencies, both for the entirety of the skin layer [46] and for each layer in particular [47-49]. In general, the living epidermis has higher resistivity than the dermis, while the resistivity of the dermis is not as variable. The higher the number of available ions the lower the resistivity values [50]; since the dermis is more hydrated it is reasonable that it has a higher ion content and therefore a lower resistivity [51]. The main component of impedance is the stratum corneum, the most hydrophobic of the skin layers [45]. Another important factor is the relevant permittivity, which reflects the amount of bound charge displacement or polarisation, in a given area, under the influence of an applied electric field [52]. This property is frequency-dependent and is influenced by the existing conditions at a cellular and molecular level [53-55].

In this review, we will present the most important research regarding the determination of acupuncture points and meridians, mostly based on the measurements of electrical parameters, in an effort to interpret their different and sometimes contradictory results. We will also try to interpret these results in the context of the general biological properties of the skin and underlying tissues. As it will become evident, there are a multitude of different studies and methods and we allude to as many of them as reasonably possible, but we have chosen to present in tables only those researches which have focused in measuring electrical properties using electrodes, as this is the focus of our paper. Finally, we will offer possible explanations for the observed phenomena, based on recent discoveries, and directions for future research.

TCM MERIDIANS AND RESEARCH ON THEIR EXISTENCE

There are numerous types of meridian groups, but here, for research purposes we will focus on the 12 principal meridians and the 2 most important extraordinary meridians (Table 1) – to our knowledge no research on locating any other type of meridian, such as collateral or connecting meridians, has been performed using modern methods.

As limb localisation, based on TCM, we define the limb on which most of a meridian’s points can be located; most often it also contains the point of origin of the meridian. The time of maximum activity for each meridian indicates when its most active for therapy, and may correspond to the modern concept of circadian rhythms, which has been discussed in many clinical contexts [59-62].

The 12 principal meridians are associated with organs of the human body, although the properties of these organs do not always correspond to those attributed to them by Western Medicine, and medical acupuncture research. For example, in TCM, the Pericardium Meridian corresponds to the ‟organ” of pericardium, which is however recognised only as an anatomical structure surrounding the heart, and not an organ proper [63,64]. Moreover, Du Mai and Ren Mai do not correspond to any organ but are associated with the regulation of other processes and functions [65,66].

In another example, the Lung meridian is associated with skin health in TCM, a seemingly paradoxical connection by Western medicine standards; however, according to a number of studies, pulmonary pathologies have skin-related manifestations, as is the case, for example of chronic obstructive pulmonary disease [67,68], and of recurring pulmonary capillaritis [69]. In a reverse example, some skin disorders in children have pulmonary manifestations [70]. While these remarks are interesting and point to a corroboration of many of the principal tenets of TCM, the mainstay of research on verifying the existence of meridians is concerned with identifying them based on their different electrical properties.

Table 1: Principal TCM meridians and their principal characteristics
(based on Soulié de Morant [56], Liangyue et al. [57], Tilikidis [58], and Periferakis [6]).

Western Meridian Name	Chinese Meridian Name	Limb Localisation	Point of Origin	Acupuncture Points in Meridian	Time of Maximum Activity
Lung	Taiyin	Hand	Upper lateral chest, approximately at the level of the 1st intercostal space	11	0300-0500
Large intestine	Yangming	Hand	Radial end of the distal phalanx of the index finger, near the corner of the nail	20	0500-0700
Stomach	Yangming	Foot	Under the eye, directly on the line traversing the pupil, between the eyeball itself and the infraorbital ridge	45	0700-0900
Spleen	Taiyin	Foot	Medial side of the big toe, near the corner of the nail	21	0900-1100
Heart	Shaoyin	Hand	Apex of the axillary fossa	9	1100-1300
Small Intestine	Taiyang	Hand	Ulnar side of the distal phalanx of the little finger, near the corner of the nail	19	1300-1500
Urinary Bladder	Taiyang	Foot	Near the eye in the depression near the inner canthus	67	1500-1700
Kidney	Shaoyin	Foot	Sole of the foot, in the depression former with the foot in plantar flexion	27	1700-1900
Pericardium	Jueyin	Hand	In the 4th intercostal space, by the nipple laterally	9	1900-2100
Triple Boiler	Shaoyang	Hand	Ulnar side of the distal phalanx of the ring finger near the corner of the nail	23	2100-2300
Gall Bladder	Shaoyang	Foot	Lateral to the outer canthus, on the lateral side of the orbit	44	2300-0100
Liver	Jueyin	Foot	Lateral side of the big toe near the corner of the nail	14	0100-0300
Governor Vessel	Du Mai	-	Under the tip of the coccyx	28	-
Conception Vessel	Ren Mai	-	Perineum	24	-

Previous studies on the identification of meridians based on their electrical properties

In general, and compared to the studies on individual acupuncture points, which will be presented on the next section, meridian studies are characterised by a larger sample size and are thus of a higher statistical significance. A number of different measuring techniques were used, and this raises the issues of the comparability and reproducibility of results (Table 2). Probably the earliest research on the different electrical properties of meridians was conducted by Nakatani [71], in the 1950s.

The research of Reichmanis et al. [72] calculated electrical parameters between two different acupuncture points of the same meridian, and determined, using Laplace analysis, that the electrical resistance values were lower. Between the line connecting the two acupuncture points studied, the 14th and 12th of the Large Intestine meridian, there was no other acupuncture point, which could potentially alter the measurements. In the same year, the same authors used the same experimental setup to calculate electrical resistance between the 3th and the 4th acupuncture point of the Heart meridian, with similar positive results [73].

The research of Reichmanis et al. [74] this time measured the resistance between two non-acupuncture points on the Heart meridian; again skin impedance was significantly lower, compared to the control area. This indicates that the presence or absence of acupuncture points in a given meridian area does not affect the clearly different electrical properties of the meridians.

The study of Ogata et al. [75], while not focused on finding the location of meridians based on their electrical properties – indeed it took for granted that the meridians are located on the trajectories described by Traditional Chinese Medicine – detected that there were significant differences in the electrical resistance values of meridians during the different stages of general anaesthesia. We consider the fact that all 12 of the studied meridians had such variations is an, at least indirect, corroboration of meridian location based on different electrical properties, and this is why we included this research. Moreover, we have also included this research in the acupuncture points section of this paper, given that the meridian resistance values were calculated as averages from a number of distinct points in each meridian. Similar results, albeit of a lesser magnitude, were noticed by Ogata et al. [76] in patients under local anaesthesia. Due to the smaller extend of the electrical resistance fluctuation we classify the findings of this research as ambiguous.

It is important to note that the electrical parameters of the skin during post-surgical resuscitation are known to vary, based on the research of Bubnova et al. [77], but it is uncertain if this phenomenon has any bearing on the two aforementioned researches.

Following electrical stimulation at the Jing point of the Stomach (45th of the meridian), 98% of the patients, from a sample of 51 patients tested in an acupuncture clinic, were found to exhibit altered impedance values across the Stomach meridian [78]. The research of Hu et al. [79], which used a larger sample, compared to most of the research efforts examined in this paper, determined that the majority of low impedance points, in the areas examined, where found within a distance of less than 5 mm from acupuncture meridians. Interestingly, they performed this test for all 14 main meridians. A year later, Hu et al. [80] used an electrode moving at an even velocity over the forearm, and computer plotting to demonstrated that most of the detected low skin impedance points were located within the traditional courses of TCM meridians. Similar results were produced by Huang et al. [81], although few details exist on their experiments.

During the research of Zhang et al. [82], impedance was found to be lower in meridians, compared to other skin regions, and to change during needling, a process potentially associated with interstitial fluid fluctuation caused by neuronal reflexes. The research of Martinsen et al. [83], performed using a sample of 20 healthy subjects, did not discover any low resistance trajectories on the volar aspect of the forearm. However, the accuracy of the measuring method of this research has come into question [84]. A subsequent research by Johng et al. [85] yielded positive results, while the research of Ahn et al. [86] had ambiguous findings, in that it demonstrated that the impedance along the Pericardium meridian was decreased, but this was not the case for the Spleen meridian.

The research of Spaulding & Chamberlin [87], who performed acupuncture in order to measure the conductivity across the Large Intestine meridian, yielded statistically significant differences in favour of the meridian, but these were not pronounced enough; thus, we regard these results as being ambiguous.

Table 2: Basic characteristics and outcomes of research of the location of meridians based on their electrical properties

Authors & Reference	Year of Study	Sample Size	Healthy Individuals	Control	Current Used	Experimental Setup	Results	Evaluation
Reichmanis et al. (73)	1977	10	Yes	1-1.5 cm parallel lines medially and parallelly	DC, 1 V	1 cm carbon-impregnated conducting rubber electrodes (modified LIDC electrodes by Ritter Co.)	The electrical resistance values in the line connecting the two acupuncture points were lower compared to the control	Positive
Reichmanis et al. (72)	1977	10	Yes	1-1.5 cm parallel lines medially and parallelly	DC, 1 V	1 cm carbon-impregnated conducting rubber electrodes (modified LIDC electrodes by Ritter Co.)	The electrical resistance values in the line connecting the two acupuncture points were lower compared to the control	Positive
Reichmanis et al. (74)	1979	10	Yes	1.5 cm parallel lines medially and parallelly	DC, 1 V	1 cm carbon-impregnated conducting rubber electrodes (modified LIDC electrodes by Ritter Co.)	The electrical resistance values in the line connecting the two non-acupuncture points were lower compared to the control	Positive
Ogata et al. (75)	1983	10	No	None	AC*	Standard ECG electrodes taped over the chosen acupuncture points in each meridian; values measured during various intervals from preanaesthesia to postanaesthesia	There was a decrease of up to 36 % in skin resistance in 10 of the 12 studied meridians, and by a maximum of 100 % and 73 % on the kidney and bladder meridians respectively	Positive
Ogata et al. (76)	1983	6	No	None	AC*	Standard ECG electrodes taped over the chosen acupuncture points in each meridian; the values were measured before and after the application of local anaesthesia	There were fluctuations of a rather small scale in all of the meridians studied	Ambiguous

Xiang et al. (78)	1984	51	No	None	AC, 0-100 V	Stimulation of the Stomach Jing point using a bipolar electrode and measurements based on the process of Zhu et al. (88)	A distinctly localised meridian line for the Stomach was located in the overwhelming majority of subjects after the initial stimulation	Positive
Hu et al. (79)	1992	68	Yes	Areas laterally removed from the meridians	DC, 0-50 V	1 mm pure Ag tip electrode	The majority of the studied points within less than 5 mm from all 14 main meridians was found to have low impedance	Positive
Hu et al. (80)	1993	12	Yes	Areas not belonging to established meridians	AC†	Exploratory electrode moving at a standard velocity over the forearm – computer system used for plotting	Low skin impedance points (LSIPs) were discovered and were generally distributed along known meridian courses	Positive
Huang et al. (81)	1993	25	Yes	Areas not belonging to established meridians	AC†	n/a (perhaps similar to the setup of Hu et al. (80))	Low skin impedance points (LSIPs) were discovered to lie mostly within or very near to known meridian courses	Positive
Zhang et al. (82)	1999	12	Yes	Non-acupuncture points in surrounding skin	AC	4 electrode technique – 4 mm diameter pipes with saline cotton	There was a decrease in impedance in the meridian area studied, which fluctuated during needling	Positive
Martinsen et al. (83)	2001	20	Yes	None	AC	16 electrode (0.5 mm diameter) linear array	No linear low resistance trajectories were detected	Negative
Johng et al. (85)	2002	30	Yes	Lateral parallel control at a distance of 6-7 cm from the tested meridian	AC	4 electrode technique similar to that of Zhang et al. (82)	Higher capacitive effects at acupuncture meridians, compared to the control	Positive
Ahn et al. (86)	2005	23	Yes	Control segments 0.8 cm distant, medially and parallelly to the tested meridians	AC	4 electrode method (0.25 mm Au plated needles serving as the electrodes) supplemented by ultrasound imaging of the connective tissue planes along the tested meridians	While impedance in the case of the Pericardium meridians was indeed lower, the same cannot be said for the impedance of the Spleen meridian	Ambiguous
Spaulding & Chamberlin (87)	2011	20	Yes	Non-meridian tissue	AC†	A test configuration involving a data acquisition hardware, while processing was performed in Matlab; acupuncture was performed during the measurement	There is a somewhat better conduction along the Large Intestine meridian, compared to non-meridian tissue; while there is a statistical significance of the values, these are not dramatic	Ambiguous

** For these researches the exact data on the type of current used are not available; therefore, based on their use of ECG electrodes and apparatuses we have assumed that it is AC current (this being the more common modality in such machines)*

† Similarly, no data on the current type were mentioned and we have assumed it to be AC, which is the most common setting

The particular research parameters of the aforementioned studies on meridian locations are presented in the table below (Table 3).

As can be seen, meridian studies have a higher mean sample size, compared to the acupuncture point studies, which will be presented in the following chapter. In general, there is a greater homogeneity of in research methods and subject selection compared to the following studies on acupuncture points presented in the next section.

The studies with control have also used healthy subjects and there is about an equal number which used AC and DC; most of them have results which can be evaluated as “successful’’. The fewer and more diverse studies with no control have also had a relatively positive total outcome. Of course, it is easier to locate meridians compared to acupuncture points, as acupuncture point location is a more difficult and precise process.

In the next subsection, a number of studies on locating meridians using other methods were presented. The association between meridians and interstitial fluid has also been explored by a number of authors along with a number of other proposed alternatives

Table 3: Data on the presented research on meridians

Study Type	N	Mean Sample Size	Subjects' Health			Type of Current Used			ReportedOutcome		
			Healthy	Not Healthy	Mixed	AC	DC	Both	Positive	Ambig.	Negative
Studies with control	10	22.00	10 (100%)	0 (0%)	0 (0%)	6 (60%)	4 (40%)	0 (0%)	8 (80%)	2 (20%)	0 (0%)
Studies with no control	4	21.75	2 (50%)	2 (50%)	0 (0%)	4 (100%)	0 (0%)	0 (0%)	2 (50%)	1 (25%)	1 (25%)
Total studies number	14	21.90	12 (85.7%)	2 (14.3%)	0 (0%)	10 (71.4%)	4 (28.6%)	0 (0%)	10 (71.4%)	3 (21.4%)	1 (7.2%)

For example, Li & Zhao [89] proposed that meridians may coincide with the courses of some blood vessels, while Zhu [90] proposed that the meridians as explained by the TCM are, in fact, an erroneous representation of the nervous system. Several hypotheses were proposed by Zhang [91] while the current research consensus focuses on the meridians representing low hydraulic resistance channels associated with the movement of interstitial fluid and specific metabolites [92]. The association of meridians with stem cells was also proposed by Pawitan [93]; bearing in mind that the stem cell potential varies with a number of factors [94-100], this could have a bearing on the differences in meridian studies across individuals.

Other Studies and Theories on the Properties and Location of Meridians

Apart from the more traditional method of detecting and/or identifying meridians based solely on their different electrical properties, a number of authors have tried a variety of different approaches (Table 2). The most probable explanation is that the different electrical properties of meridians are based on a neural electrical field [101].

The tentative research of Jiang et al. [102] indicates that along meridians, the microcirculatory response to moxibustion therapy is different; thus it may be inferred that there may be well be some level of difference in the microvasculature of meridians, compared to other locations on the body. Research suggests that, in rat experiments, moxibustion therapy seems to modulate gene expression [103]. A clinical trial protocol on the same principle was proposed by Hu et al. [104]. On a different note, the research of Lin et al. [105], indicated that the electrical flow across meridians changes depending on acupuncture needle manipulation during therapy.

Crucially, as is also the case for certain acupuncture points, the electrical properties across meridians seem to differ between pathological and healthy conditions [106,107]. On a related note, a potential association between electrical resistance changes and pain after orthopaedic surgery, which however warrants further investigation, was proposed by Rezvani et al. [108].

The most currently prominent avenue of research on defining the morphofunctional characteristics of meridians centres on them being supposedly channels where a higher amount of interstitial fluid is found. A gel model based on this concept seems to suggest that there is some merit in this theory [91]. An earlier research by Zhang et al. [109] in rats, had not produced any corroborating results.

Finally, the different electrical properties of meridians may be associated by an ion drift theory, as proposed by Liu et al. [110]; notably the research of Lee et al. [111] also mentioned that the special properties of acupuncture points may be associated with different ion concentrations.

VARIATION OF SKIN ELECTRICAL PROPERTIES AT ACUPUNCTURE POINTS

The classical Chinese theory postulates that there exist over 300 acupuncture points, distributed across the 12 principal and 2 extraordinary meridians mentioned above, all over the human body.

The stimulation of these points, based on the view of traditional acupuncturists, adjusts the “qi flow” along the human body; the most frequent proposed interpretation for this notion of “qi energy” is electrical energy [112] and this has been the focus of the majority of meridian detection-associated research.

Electrical properties of acupuncture points – Research history

While, based on the traditional theory, the location of points is determined based on the anatomical parameters and locations of the human body, it was though also possible that these points exhibit distinct electrical properties; based on this speculation, relevant research was performed in the 1950s ([33,113]; and references therein), documenting that at least some acupuncture points where characterised by specific electrical properties.

Table 4: Basic characteristics and outcomes of research of the location of acupuncture points based on their electrical properties

Authors & Reference	Year of Study	Sample Size	Healthy Individuals	Control	Current Used	Experimental Setup	Results	Evaluation
Reichmanis *et al.* (122)	1975	7	Yes	Anatomically similar location within 1 cm^2	DC, 8 V	1.5 mm measuring electrode and a specially designed wheel electrode; both made from stainless steel	Most of the acupuncture points measured were identified based on their electrical parameters in all subjects	Positive
Reichmanis *et al.* (123)	1976	10	Yes	Suitable nearby anatomical location	DC, 2 V	36 stainless steel rods in a grid pattern over the acupuncture point	Over 75% of the acupuncture points were electrically different compared to the control areas	Positive
Hyvärinen, & Karlsson (124)	1977	5	Yes	Surrounding skin	DC, 6.7 V	0.5 mm circular electrode and 2.5 mm reference electrode	Points of consistently low electrical resistance, resembling acupuncture points, were identified	Positive
		5	Yes		DC & AC	0.5 mm silver wire	Massively lower, about 50-100 times, electrical resistance was identified in the same points as above	Positive
McCarroll & Rowley (125)	1979	8	Yes	None	AC (V is a measured variable)	5 x 5 grid with the acupoint in the centre	The decreased electrical impedance detected at a few points was attributed to temporal variations and the pressure of the probe on the stratum corneum	Negative
Poon et al. (127)	1980	9	Yes	Surrounding skin	AC, 0-18 V	Special epiductive tape electrode	Numerous spots of increased conductance were identified, many lying across the meridians, but a lot differing significantly from conventional acupuncture locations	Ambiguous
Jakoubek & Rohlícek (129)	1982	n/a	n/a	n/a	DC & AC	Multiple electrodes	Many points with increased electrical conductance, corresponding to acupuncture points, were detected	Positive
Ogata et al. (75)	1983	10	No	None	AC†	Standard ECG electrodes taped over the chosen acupuncture points in each meridian; results measured during various intervals from preanaesthesia to postanaesthesia	There were marked electrical resistance variations during the different stages of anaesthesia, in most of the acupuncture points studied	Positive
Ogata et al. (76)	1983	6	No	None	AC†	Standard ECG electrodes taped over the chosen acupuncture points in each meridian; the values were measured	There were fluctuations of a rather small scale in all of the individual points measured	Ambiguous

						before and after the application of local anaesthesia		
Margolin et al. (131)	1996	34	No	Auricular control zones not comprising any acupuncture points	DC	Specially developed device with a 1 mm Ag/AgCl electrode composition; use of biogel as a conducting medium – the measurements were performed using auricular acupuncture points; subsequent acupuncture of both control and active points was performed	The therapeutic effects of acupuncture in low impedance points were not very much different from the effects on non-acupuncture points	Ambiguous
Zhang et al. (82)	1999	12	Yes	Non-acupuncture points in surrounding skin	AC	4 electrode technique – 4 mm diameter pipes with saline cotton	There was a decrease in impedance in the meridian area studied, which fluctuated during needling	Positive
Falk et al. (130)	2000	34	No	Control zones on the helix of the ear	AC	An Ag/AgCl probe of 1 mm diameter in a 2 x 2 grid	The sites of lowest impedance were identified as being within active zones	Positive
Zhang et al. (138)	2004	12	Yes	Two points on either side of the low impedance points at a distance of 0.5 cm	AC	Four-electrode impedance instrument (Korean SPAC instrument) based on the methodology described by Zhang et al. (82)	It was found that 71 % of the acupuncture points tested had a lower impedance compared to the control points	Positive
Lee et al. (139)	2005	20	Yes	One non-acupuncture point	DC, 1.28 V	Electrodes affixed to two acupuncture points and one non-acupuncture point; constant pressure applied in the 4th point of the Large Intestine Meridian	Meridian points exhibit a greater conductivity compared to non-meridian points	Positive
Pearson et al. (141)	2007	20	Yes	Nearby control sites no more than 5 cm away from the acupuncture points	DC & AC	Prognos instrument (4.57 mm probe tip) along with a specially designed PT probe	None of the acupuncture points measured exhibited lower impedance values compared to the control points	Negative
Kramer et al. (142)	2008	43	Yes	Surrounding skin	DC, 4.8 V (mean)	Specially designed array comprising 64 electrodes covering an area of 36 cm^2	Only about 1/3 of the measured acupuncture points exhibited significantly decreased electrical resistance values	Negative
Kramer et al. (143)	2009	53	Yes	Surrounding skin	DC, 4.8 V (mean)	Specially designed array comprising 64 electrodes covering an area of 36 cm^2	Some acupuncture points displayed elevated and some reduced impedance values compared to the surrounding areas; it is therefore considered possible that acupuncture points possess different transient electrical properties compared to the surrounding skin	Ambiguous
Rezaei et al. (144)	2012	18	Yes	Parallel series of four control needles placed 0.8 cm	AC	4 electrode technique specifically designed for the study in question	The point studied (PC4) was found to be electrically distinct from other non-meridian points and similar	Positive

				medial to the meridian needles			to other points of the same meridian	
Wong (145)	2014	65	Yes	A neighbouring non-acupuncture point, 2 cm distant	DC, 0.5 V	Bipolar electrode (3 mm in-between electrodes) and a sensing probe	The point studied (LI14) was not found to be electrically distinct from the control point	Negative

** For these researches the exact data on the type of current used are not available; therefore, based on their use of ECG electrodes and apparatuses we have assumed that it is AC current (this being the more common modality in such machines)*
† Similarly, no data on the current type were mentioned and we have assumed it to be AC, which is the most common setting

Some decades earlier, in the 19th century, August Weihe (1840-1896), a medical doctor and homeopathy practitioner came to the conclusion that specific points in the human body were found to be more painful compared to the others, following the ingestion of a toxic quantity of certain homeopathic remedies [114]; it has been mentioned that Weihe knew the notion of specific therapeutic points from a relative in China [115]. It is also notable that Soulié de Morant mentioned that these points coincided with Chinese acupuncture points [116]. The theory of homeosiniatry was proposed by Roger de la Fuye (1890-1961), in 1932, to account for the physiological similarities between homeopathic remedies and acupuncture points; notably, he impregnated some acupuncture needles with homeopathic remedies in a number of his acupuncture therapies [116]. Today, both Weihe and de la Fuye are considered as the ancestors of the theory of electroacupuncture [117]. In 1953, probably the first electroacupuncture apparatus was designed and built by R. Voll (1909-1989) and F. Werner [113].

Despite many studies having taken place on this subject (Table 4), some of them are deemed as being of poor quality, due to a number of factors [118]. A particular point in researching the electrical properties of acupuncture points is the standard to which the data obtained are compared with; more precisely, while acupuncture points may not present minimal electrical resistance at an absolute level, the issue is if they exhibit a different electrical resistance compared to their surrounding tissues. Dedicated research to for the particular, if any, electrical properties of acupuncture points began in the 1970s; notable research efforts from this era are those of Frost & Orkin [119] and Kaslow [120]. Contemporary views on the existence and function of acupuncture points in particular and acupuncture in general can be found in McCarroll [121].

The research of Reichmanis et al. [122] was based on the principle that acupuncture points exhibit a reduced electrical resistance [30]; accordingly, they aimed to prove that acupuncture points exhibited a distinct resistance minimum compared to the surrounding tissue. They employed direct current and used some of the most easily accessible points of the Large Intestine (LI) and Pericardium (Per) meridians; they concluded that all of the studied points exhibited an increased electrical conductance, relevant to the surrounding tissues and most could be located in the majority of subjects. In a subsequent research [123], using a 36 rod grid, on skin disinfected with 90 % alcohol and moistened with tap water, over selected acupuncture loci; suitable control areas were also selected. The points selected were again easily accessible, from the Triple Boiler (TB) and Lung (Lu) meridians. Most, but not all, points were detectable based on different electrical parameters. Further promising results were obtained by Hyvärinen & Karlsson [124], who detected a number of low electrical resistance points on the forearm, hands and ears, which resembled acupuncture points, albeit in a small sample of five healthy individuals. Similarly, in these points the electrical impedance values were found to be massively lower compared to the surrounding skin [124].

Despite these positive results, McCarroll & Rowley [125], who measured the electrical conductance in certain acupuncture points in the hands and arms, came to an unfavourable conclusion. It is noteworthy that this study considered extensively the probable consequences of the pressure applied by the electrode on the skin, to the measurements; in addition, it considered whether any break in the stratum corneum may influence the results. The authors mentioned that, based on their measurements, the time-dependent nature of skin conductance, as asserted by Geddes & Valentinuzzi [126], applied to their measurements as well. They concluded that any detected variations were the result of differing electrode pressure on the stratum corneum and the temporal variability of skin conductance [125].

In an effort to minimise the effect of the electrode itself, Poon et al. (127) used a special epiductive tape electrode, based on the method of Burton & Maurer (128). They determined that a number of points which had different electrical properties corresponded with acupuncture points, but other such points did not; moreover, no statistical analysis demonstrated that across all subjects no significant coincidence between electrically "special" points and acupuncture points was revealed. Even more strikingly, the points of good conductance differed between the two arms of the same subject (127). In addition, a number of low resistance points coinciding with acupuncture points were detected in both humans and rats, and also some such points – not corresponding to acupuncture points – were found in areas of referred pain (129). The research of Ogata et al. (75), to which we have already referred to in the meridians section, also noted that electrical properties of acupuncture points changed during different stages of anaesthesia. For the same reason, the other research of Ogata et al. (76) is included in this chapter too.

A four-electrode method was employed by Zhang et al. (82) to evaluate a single acupuncture point, the 3rd of the Pericardium meridian, during, before and after needling, compared to a number of control points. It was noted that electrical impedance changed in all points, but the impedance reduction in acupuncture points was greater; it was theorised by the researchers that the impedance decrease was owed to a transient increase of interstitial fluid during needling, which is most probably associated with an axonal reflex and/or blood capillary expansion (82). We have already included this research in the section on meridians, but we also place it here because of its focus on the area around a single point.

Meanwhile, Falk et al. (130), using as test subjects patients under treatment for cocaine addiction, detected significantly lower impedance values in the active zones of the ear, i.e. those corresponding to auricular acupuncture points. A similar research had already been conducted by Margolin et al. (131), who tested the differential efficacy of acupuncture treatment in high and low impedance points in the ear; the results in this clinical trial had been ambiguous, in that while needling in low impedance points – corresponding to acupuncture points – had somewhat better effects, this difference was assessed as not being significant enough. Again, this therapeutic approach concerned auricular acupuncture in cocaine addicts. Interestingly, during auricular acupuncture it proved impossible for the subjects to identify, based on pain perception, when acupuncture points were needled, or when needle placement was random (132). Incidentally, there is as of yet no consensus regarding the efficacy of auricular acupuncture in treating cocaine addiction; the results range from mildly encouraging (133, 134) to inconclusive (135, 136) or even negative (137).

Using the four-electrode method, Zhang et al. (138) determined that in their research on a small number of heathy subjects, 71 % of the acupuncture points had a significantly lower impedance compared to the control points on either side. The research of Lee et al. (139) suggested that between two acupuncture points the conductance was greater than between a non-acupuncture and an acupuncture point. Since the second pathway did not belong to an established meridian, they concluded that their experiment perhaps corroborated the theory of Chen (140), who proposed that the dielectric constant along meridians is lower compared to other non-meridian trajectories. Contrary to this, the research of Pearson et al. (141), which was one of the most well-controlled studies, did not detect any significant differences in electrical impedance between acupuncture and non-acupuncture sites.

The research of Kramer et al. (142), who studied the variations of electrical skin resistance in the 34th point of the Gall Bladder meridian in 43 healthy volunteers concluded that, compared to the surrounding skin, only about 33% of the studied points exhibited statistically significant differences; they rightly considered such a small percentage to not be in agreement with most other performed research. A subsequent clinical trial (143) yielded ambiguous results.

The research of Rezaei et al. (144) aimed to determine if a certain acupuncture point, the 4th of the Pericardium meridian, had any different properties compared to its surrounding ones and other points in the same meridian; it was found that it was electrically distinct compared to non-meridian points, but not so much compared to meridian ones. The four-electrode method employed was based on the research of Zhang et al. (82).

The research of Wong (145) is particularly important, as it strived to do stringent lab-controlled measurement of skin resistance of an acupuncture point (14th point of Large Intestine Meridian) on a larger sample (65 participants) than other studies. In their larger sample, they found no statistically significant difference in the electrical resistance between acupuncture and non-acupuncture points.

The results from all the studies in Table 4 are presented in the following table (Table 5), in order to enable a more complete view of the current research consensus.

Table 5: Data on the presented research on acupuncture points

Study Type	N	Mean Sample Size	Subjects' Health			Type of Current Used			ReportedOutcome		
			Healthy	Not Healthy	Mixed	AC	DC	Both	Positive	Ambig.	Negative
Studies with control	15	23.1	13 (86.7%)	2 (13.3%)	0 (0%)	5 (33.4%)	8 (53.3%)	2 (13.3%)	9 (60%)	3 (20%)	3 (20%)
Studies with no control	3	8	1 (33%)	2 (66%)	0 (0%)	3 (100%)	0 (0%)	0 (0%)	1 (33%)	1 (33%)	1 (33%)
Total studies number	18	20.6	14 (77.8%)	4 (21.2%)	0 (0%)	8 (44.5%)	8 (44.5%)	2 (11%)	10 (55.6%)	4 (22.2%)	4 (22.2%)

As it can be easily seen from the aforementioned concise table on research results, the studies with control have a considerably larger sample size compared to the studies with no control, where its absence along with the limited sample size further undermines their statistical significance.

In assessing the more significant first group of studies, the overwhelming majority used healthy subjects, while half of them used direct current. Only a small percentage were negative, while the majority was positive or ambiguous. The results were equally distributed in the second group of studies; overall, about half of the studies presented in this section were unambiguously positive, although we would suggest that this statistic has been negatively skewed due to results from the studies with no controls. The majority of studies selected healthy subjects only, while the most frequent current used was alternating current by a small margin, followed by direct current; very few studies opted for both currents.

The relative discrepancy in results can be partly, in our opinion, explained by the fact that the majority of studies have limited their measurements in the upper limbs. The most recent research indicates that acupuncture point resistance values are non-linear [146] and this may influence the results, because on one hand some researches may have focused in non-optimal areas, and on the other few data on the lower parts of the body, and the head exist, if any at all. It is, however, a fact that electrical resistance measurements exhibit great variations depending on anatomical locations [118].

A curious phenomenon, termed the “drift” effect, was discovered by Mayer-Gindner et al. [147], where, if alternating current (AC) is used by the electrode, in the same point, gradually the electrode-skin resistance will decrease. They proposed that at least 20-30 min, if not 40-50 min should pass between two consecutive measurements, even if the point measured is not the same but an adjacent one. They suggested a new method for locating acupuncture points using alternating current. However, this does not seem to be the case, at least to our knowledge, as 5 out of 6 control-group AC studies yielded a positive result.

Presumably, the same influence of the circadian rhythm on meridians, if confirmed, should apply also to acupuncture point measurements. It is known for certain that the circadian rhythm affects skin physiology [148]. The circadian rhythms are also known to affect skin hydration [149], a factor which for sure influences the electrical resistance of the skin and potentially the detectability of acupuncture points.

In addition, there are evidence which suggest that the partial oxygen pressure values in the tissues underlying the meridians are higher than the tissues under random anatomical sites [150]. We mention this research here, instead of the previous meridian chapter, since it was performed on acupuncture points but in essence concerns the whole meridians trajectories. The extensive scientific literature in matters other than electrical properties per se, as outlined in the previous section, seems to corroborate the existence of acupuncture points as distinct morphofunctional entities.

We may conclude that regardless of whether the loci of low electrical resistance can be considered as being the same as the acupuncture points of TCM or not, it is by far more probable that such distinct loci do exist. Their diameter ranges from 1 mm to about 4 mm [120,151,152]. A factor which complicates matters is the relative uncertainty in locating acupuncture points [153], as based on textbooks there may be slight variations [154]; taking into account the tiny diameter of the loci of decreased resistance, it is conceivable that some negative research outcomes were influenced by a slightly erroneous choice of measurement sites. Research on whether needling of the exact location is necessary for a successful treatment outcome is still ongoing [155]; perhaps a general location with a diameter of some mm with the locus of minimum impedance at the centre may be considered as an acupuncture point. What is more certain is that the stimulation of acupuncture points, or of areas around them at least, is by far more effective that the stimulation of random, non-acupuncture points, based on a number of studies [156-160].

Other studies and theories on the properties of acupuncture points

There are a number of other studies, which are associated with the particular properties of acupuncture points, but which do not adhere to the pattern thus described, i.e., the comparison between acupuncture and non-acupuncture points in terms of their electrical properties. The effort of morphologically defining acupuncture points has begun since the late 1970s [161] and it is still an ongoing field of research, where many suggestions and research results must be taken into account. From a structural standpoint, it has been proposed that the microvasculature is capable of providing a larger blood supply in acupuncture points [162].

For example, Liang et al. [163] have asserted that the NO (nitric oxide) concentration in the skin, in acupuncture points, is higher compared to non-meridian and non-acupuncture points. According to their experiment, a NO-noradrenaline system is associated with the different electrical resistance at acupuncture points. Their experiment was based on the previous findings of Chen & Ma [164]. In the same year, Ma [165] asserted that, in addition to the NO-noradrenaline system, the reduction of nitrates by bacteria at acupuncture points was also contributing to the different electrical properties. Other relevant studies, with quite favourable results also exist [166-169].

A limited research effort by Khorsand et al. [170] used an entirely different setup, in that it evaluated the changes of electrical properties of acupuncture points before and after acupuncture was performed – none were detected. A study by Turner et al. [171] aimed to ascertain whether, between arthritis patients which experienced pain and pain-free arthritis patients, there would be any difference between the electrical properties of certain acupuncture points. They concluded that patients which felt pain had different resistance values at acupuncture points, and ventured to suggest that the different electrical energy flow in these patients might be seen as a connection between Western and Chinese medicine concepts.

Ambiguous results, regarding menstrual pain, were yielded by She et al. [172]; the authors do remark, however, that it is a promising field for further investigation. Indeed, following a recent thermographic analysis, Xisheng et al. [173] suggested that a number of acupuncture points is sensitised in patients with primary dysmenorrhea. Interestingly, based on Xu et al. [174], the electrical resistance of specific acupuncture points changes with the variations of blood flow in the uterus, during the menstrual cycle, a result also previously yielded by the research of Wei et al. [175]. At any rate, a nerve-related model to explain acupuncture analgesia was put forward by Silberstein [176]. The values of the electrical properties of a number of acupuncture points were also found to be different in encephaloma patients undergoing surgery [177].

It is also compelling to consider the implications of the research of Weng et al. [178] who suggested that electrical conductance was different between healthy and obese patients, and in fact changed as those obese patients started losing weight.

Recently, an emerging theory suggested that at least some acupuncture points may be thermically distinct between healthy and unhealthy states [179]; this is also a promising field for future research. An earlier review on the subject [180] was more assertive in acupuncture points having a distinct thermal profile, but this is not a unanimously supported conclusion. The infrared profile of acupuncture points may also be of interest in determining the best course of acupuncture therapy [181]. Another study, focusing on asthma patients, suggests that it may be possible to use the values of electrical impedance at certain acupuncture points for screening and treatment effectiveness purposes [182].

The individuality, so to speak, of acupuncture points maybe also be attributable to their differing, compared to the surrounding tissue, ion concentrations, as suggested by the research of Lee et al. [111]. A number of inorganic ions, such as Ca2+ and Mg2+ are distributed prominently on the upper delimitation of the stratum granulosum [183-185], while the distribution of other ions varies in the other layers [184-187]. We might thus suggest, that from a morphological point of view, the distinct acupuncture points represent areas where, for some reasons, there is a differential horizontal and lateral ion distribution across the skin layers. Interestingly, given that the upper stratum corneum is permeable to external substances [188-191], its ionic profile can theoretically be externally modified; thus, by modifying the electrical resistance of acupuncture points it may be possible to modify treatment efficacy.

It must also be noted that, according to the review of Colbert et al. [192], there is an important clinical utility in assessing the variations of electrical properties in acupuncture points, given that they might reveal latent pathologies or be associated with a state of physical exhaustion. The stimulation of acupuncture points with chemical means, also has therapeutical effects as suggested by a number of researchers [193-196]. Regarding this aspect, it is interesting to remark that drug administration in acupuncture sites seems to be more effective compared to non-acupuncture sites [197]. Furthermore, the research of Periferakis & Periferakis [198], in a sample of 40 patients, both healthy and not, using the Pointo Select DT device, for detection of auricular acupuncture points, determined that in the majority of cases, most, but not all points are easily detectable.

An interesting concept is that of neuronal acupuncture [199], which is based on the premise that in acupuncture points, specific neuronal and neuroactive components are stimulated; these loci could comprise the 361 WHO-accepted acupuncture points [200]. The concept of neuronal acupuncture could perhaps be used to explain how or why acupuncture points exhibit different electrical properties, compared to the surrounding skin.

Finally, Cho et al. [201] measured biopotential differences between acupuncture and non-acupuncture points during acupuncture treatment; acupuncture points seemed to have greater variability which seems to be related to the classical concept of the "flow of Qi". Even the practicing of Qigong, which is theorised to affect Qi circulation, results in significant changes of the electrical potential of acupuncture points [202]. It has also been documented that with needle placement in certain acupuncture points it is possible to observe electrocardiogram and electroencephalogram changes [203,204]; changes where affected during stimulation of non-acupuncture points also, but needle placement in acupuncture points produced more pronounced changes [204].

DISCUSSION

Research on the properties of acupuncture points and meridians has been one of the most prominent topics amongst relevant scholars [205]. It is obvious from the presented studies, that many different researchers have evaluated the identification of acupuncture points based on their electrical parameters, but many of these methods differ significantly, and it is little wonder that their results are not comparable. Of particular interest, however, is the fact that the voltage selected each time seems not to affect the results, i.e., a different voltage will not turn a low impedance point into a high impedance one [206], so at least this offers a modicum of result comparability even if the experimental parameters differ.

Nonetheless, it must be stressed that a host of factors from the parameters of the electrodes, to the physiological and psychological status of the subjects, to the frequencies used, affect the detection of low impedance points [85,207]; therefore, many research results may be rendered inaccurate, and this may also explain the discrepancies in-between the values even of positive-outcome research efforts. Another research by Prokhorov et al. (208) suggest that between racially different populations, the DC measurements of skin resistance are not comparable, a factor which must also be taken into account in future studies. A useful summary of confounding factors in acupuncture point detection research is provided by Luo et al. [209]. It should be noted here that considerable variations in the localisations of acupuncture points is a fairly common occurrence even amongst experienced acupuncturists [210], i.e., the discrepancies are not limited to apparatus-based location methods.

Current research efforts and their significance

Based on the cumulative research results on both the meridian and acupuncture studies (Table 6) we can see that the majority of them where positive, in that it was possible to identify electrically distinct locations and lines on the surface of the human body. Most of the studies used DC, although an almost equal number used AC, and only 2 used both types of current. Finally, the mean sample size was 21.2 subjects. It is difficult to conclude here what the optimal sample size should be for such a research, as there are quite a number of factors which influence its size [211]; moreover, the statistical significance of a sample does not directly in itself validate the experimental results [212]. However, since meridians and acupuncture points, should, in principle, be detectable in any individual, for this particular type of studies, even a small sample should suffice to determine the outcome. However, as mentioned by Reichmanis et al. [123], not all acupuncture points are detectable at all times, and this may be important for the therapeutic efficacy of acupuncture in different patients, or for different protocols used on the same patient. Anomalies in the detectability of acupuncture points, specifically for auricular acupuncture, have been reported by Periferakis & Periferakis [198].

Table 6: Combined and comparative data on the detection of acupuncture points and meridians based on their electrical properties

Study Type	N	Mean Sample Size	Subjects' Health			Type of Current Used			ReportedOutcome		
			Healthy	Not Healthy	Mixed	AC	DC	Both	Positive	Ambig.	Negative
Studies with control	25	21.9	23 (92%)	2 (8%)	0 (0%)	11 (44%)	12 (48%)	2 (8%)	17 (68%)	5 (20%)	3 (12%)
Studies with no control	7	20.6	3 (42.9%)	4 (57.1%)	0 (0%)	7 (100%)	0 (0%)	0 (0%)	3 (42.8%)	2 (28.6%)	2 (28.6%)
Total studies number	32	21.2	26 (81.3%)	6 (18.7%)	0 (0%)	18 (56.3%)	12 (37.5%)	2 (6.2%)	20 (62.5%)	7 (21.9%)	5 (15.6%)

A number of meridian and point locator devices have entered the market after the 1970s [138]. Given the differences in approaches and the fact that even with complicated experimental setups results cannot always be obtained, it is no wonder that the efficacy of early acupuncture point detectors, based on the properties of the points themselves, was called into question [213]. Newer and more sophisticated devices and sensor arrays, such as those proposed by a number of authors [214-216] may improve detection results and eliminate ambiguity.

Regarding research purposes, the delayed luminescence method [217] and the low energy laser (LEL) coherent light interaction with skin [218] may be of future use in evaluating the dielectrical properties of acupuncture points. The more modern method of electrodermal mapping may prove even more useful [219]. Indeed, in the recent years measuring reliability seems to have improved considerably [220].

Finally, the variations and importance of electrical resistance will prove useful even in considering the physical composition of the needles themselves; recent evidence suggests that by some specific material treatment methods it is possible to affect electrical resistance and therefore the therapeutic potential of the treatment [65]. At any rate, as discussed elsewhere, the electrosensitivity of acupuncture points may be a useful clinical and treatment marker [221]. Bearing in mind that there are a number of proposed mechanisms for the action of acupuncture [222], there exists a host of potential modifying factors in assessing the function and potential of acupuncture points and meridians.

Potential Future Directions of Research

Regarding attempts at a structural and biological interpretation for the existence of acupuncture points and meridians, there exists a number of recent research attempts regarding evidence on a cellular level. The most recently discussed theory is that telocytes may be the underlying biological bases of meridians. This is a specialised type of interstitial cells [223], with cytoplasmic extensions; such a structural particularity enables the communication with other distant cells [224]. Telocytes have been found to reside in a number of different tissues [225-232]. Although appearing similar to some other specialised cells types, both telocytes themselves and their extensions, the so-called telopodes are structurally different [233]; the telopodes are expressed both in the body and in cell cultures [234]. There are many theories on what their exact function may be [235-238], but as of yet there is no consensus. A detailed investigation into the potential association between telocytes and TCM meridians was performed by Yonghong et al. [239], on tissues of different animals. Indeed, it was proved that there exist both homocellular and heterocellular connection between telocytes and telocytes and other cell types respectively [239]. Since telocytes interconnect smooth muscle cells, glandular cells and cells for different organs, along with nerves and other structures, this could be the long-elusive network enabling the stimulation of superficial skin structures to have an effect on distant and apparently unrelated morphofunctional units. Notably, as Yonghong et al. [239] assert, the existence of telocytes could be a basis for the interpretation of all the current meridian-associated theories proposed by numerous authors [240-244]. Despite the promising aspects of telocyte research, it must be noted that, as of yet, and to the best of our knowledge, it has proven impossible to interpret all the physiological and pathological connections mentioned in TCM using the notion of telocytes. This of course might be traced down to the fact that telocytes are dynamic cells, so that static imaging techniques may not be always able to trace the full extent of their network. Alternatively, there might be telocytes that are sometimes overlooked in research for a number of reasons [245]. Or, apart from the two aforementioned constraints, it may just so happen that telocytes are not the only answer to this conundrum. Interestingly, a telocyte-based mechanism for the cure of ulcerative colitis by acupuncture was recently proposed by Bai et al. [246].

Another theory on what is the biological basis for meridians and acupuncture points involves keratinocytes, the most dominant cell type of the epidermis [247]. Regarding their electrical activity, it is known that they possess physiologically, a variety of transient receptor potential channels [248-253], along with a number of other channels and receptors [254, 255]. Based on this aspect, and on the experimental research of Denda & Tsutsumi [256], it is hypothesised that it is possible for keratinocytes to generate spatially restricted signalling patterns, which they can then transmit to the unmyelinated nerve fibres of the epidermis [256]. While this may not explain the exact localisation of the points and meridians as proposed by TCM, it does however propose a mechanism by which the stimuli by the needle puncture can be transmitted to the unmyelinated nerves present in the skin [257] and hence affect even spatially distant areas (256). In addition, other researchers have linked acupuncture to the concept of neuroimmunology (e.g., [258-262]].

One additional research avenue is the study of the location of acupuncture points or meridians, based on the effects of phytochemicals when applied at such locations. The most prominent such efforts concern the application of capsaicin, a phytochemical with numerous beneficial properties [263-267], in acupuncture points which was found to have favourable results [268-270]. Based on the past history of use of certain compounds at acupuncture points [116], other phytochemicals, with demonstrated health-related properties, such as kaempferol [271,272], curcumin [273,274], piperine [275], pinosylvin [276], and a host of natural compounds used in the field of oncology [277], could be used experimentally, to verify or dismiss such claims. Furthermore, it is known that acupuncture can measurably influence certain hormone levels in body fluids [278,279]; therefore, we propose that clinical trials could be designed, especially in cases where hormones or their analogues could be of therapeutical benefits, such as in the case of somatostatin [280, 281].

CONCLUSION

Studies on the detection of TCM meridians and acupuncture points have been ongoing, intermittently, during the last decades, by numerous different research teams, using different experimental setups. Whereas the majority of results is positive, i.e., TCM meridians and acupuncture points can be distinguished from the surrounding skin, due to theirs having different electrical properties, there exist a number of shortcomings in most experimental efforts. To be more precise, the different parameters used in most experiments do not permit an easy comparison of results, while the small sample size oftentimes used raises questions of statistical validity; in a number of cases there is also a lack of control factors. Even though we can conclude that it is possible to detect TCM meridians and acupuncture points using electrical properties, more research efforts are needed in order to standardise the experimental approaches and find a structural or functional basis for their existence.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration for publication elsewhere. This research received no external funding.

Authors' contribution

Conceptualization, A.P., K.P.; methodology, A.P., K.P., A.I.; validation, A.P., and D.O.C.; formal analysis, A.P.; investigation, A.P., K.P., A.I., L.T., C.M.; resources, C.M.; writing—original draft preparation, , A.P., K.P., A.I., L.T., A.-T.P., C.M., D.O.C.; writing—review and editing, A.P., K.P., A.I., L.T., A.-T.P., D.O.C.; visualization, A.P.; supervision, A.P., K.P., D.O.C.; All authors have read and agreed to the published version of the manuscript.

Abstract: Background: The deficit of medical staff in various health care systems points out the need for a more detailed strategic management toward sustainability in human resources. The purpose of this study is to explore the relationships linking self-esteem, self-efficacy, general attitudes, and career preferences among medical students, aiming to provide insights that could support sustainable career development. Methods: We performed a monocentric observational study that included 157 students. The participants completed four standardized questionnaires evaluating the self-efficacy, the self-esteem, the general attitudes and beliefs, and the perception of medical career specialty. We assessed the relationships between the psychological variables and career preferences. Results: Significant correlations emerged between the students' year of study and the need for achievement, the importance of mentorship, and career decision-making. Clinical students, in particular, placed greater emphasis on gaining practical experience in their chosen field. Conclusions: Our results reaffirm the impact of occupational psychology in the health care system, providing more sustainability in career decisions. Further research involving larger and more diverse samples is recommended to gain a more comprehensive understanding of how the study of various psychological factors could impact human resources management in the field.

Keywords: human resources, sustainability, health care, self-esteem, self-efficacy, medical students, career perception, occupational psychology

INTRODUCTION

The healthcare systems experience, nowadays, an important deficit of human resources, achieving health care quality very challenging, especially in developing countries. Thus, the strategic management of human resources should use various psychological tools in order to reach stability in various medical specialties, considering the psychological characteristics of the medical students [1].

Medical students often experience chronic stress during their academic development. Thus, self-esteem, self-efficacy, and general attitudes and beliefs are

of paramount importance in the process of psychosocial growth and have a marked effect on thoughts, feelings, values, and professional goals [2]. Furthermore, future career decisions should rely on occupational psychology as a guarantee for the sustainability of the human resources in health care systems worldwide [3]. In this regard, the perception of self-esteem, self-efficacy, and general attitudes and beliefs among medical students serve as tools for occupational psychology in the field [4].

The integration of organizational psychology into the training of medical students is essential for the sustainable development of human resources in the health field. This approach contributes to preparing the future doctors for professional challenges and promoting an efficient work environment.

Self-esteem refers to the totality of the value judgments of an individual regarding their person. Both very low self-esteem and very high self-esteem can lead to psychological problems. Thus, the self-esteem should be at an average level. Self-efficacy refers to the beliefs of an individual about his or her ability to mobilize his or her cognitive, behavioral, and motivational resources to complete a task, respectively, to his/her ability to organize and execute purposeful actions. People with a high level of self-efficacy optimally allocate their resources to solve tasks successfully, whereas people with a low level of self-efficacy avoid initiating actions, withdraw from tasks, fail, and reinforce their beliefs about their incompetence in the respective tasks.

The general attitudes and beliefs refer to four dimensions: achievement, approval, comfort, and justice. With respect to cognition, it measures the global assessment of one's own person and the global assessment of the value of others, rationality, and preferences, considering the choice of students with regard to the medical specialty.

Given that medical students experience high levels of stress and are at increased risk of psychological disturbances during the learning process, self-esteem and self-efficacy may be important variables in their well-being and performance [5].

In the literature, self-esteem and self-efficacy have been associated with academic performance and job satisfaction. Recent studies have shown that these variables are interconnected and influence the perceptions and career choices of medical students [6,7].

Social perfectionism, defined by the need to meet the expectations of others, as a part of general attitudes and beliefs, can negatively affect academic self-efficacy and lead to academic burnout [8,9]. Educational interventions that support competence, learning from mistakes, and self-efficacy can reduce these negative effects [10].

Using four well-established questionnaires, which quantify the self-efficacy [11], the self-esteem [12], the general attitudes and beliefs [13], and the perception of medical career specialty [14], this study aimed to: (1) compare differences in self-esteem, self-efficacy, general attitudes and belief scores with respect to the career preferences of medical stu-dents; (2) correlate self-esteem, self-efficacy, general beliefs and attitudes scores, and ca-reer-related perceptions among medical students; and (3) identify how these variables in-fluence the career preparation and orientation of the students at different stages of their academic training.

MATERIALS AND METHODS

This research consists of a monocentric observational study that includes medical students from Carol Davila University of Medicine and Pharmacy, Bucharest-Romania, who were interviewed between March and July 2024. We enrolled 157 participants (118 females, 39 males). The mean age was 21.6 years (+/- 2.16). They were asked to answer a survey consisting of 4 scales: the Self-Efficacy Scale (SES) (10 items) [11], the Self-Esteem Scale (SS) (10 items) [12], the General Attitudes and Beliefs Scale (GABS-SV) (26 items) [13], and the Perception of Medical Career Specialty Questionnaire (PMCS) (24 items) [14]. Table 1 reveals the main items included in each scale.

Table 1: The main items included in each scale

Name of the Scale	Items included in each Scale
Self-Efficacy Scale	I always manage to solve difficult problems if I try hard enough/Even if someone opposes me, I manage to identify ways and means to get what I want/It is easy for me to be consistent with my goals and achieve my goals/I have confidence that I could successfully cope with unforeseen events/Thanks to my resources I know how to deal with unexpected situations/I can solve most problems if I put in the necessary effort/I can stay calm when faced with difficulties because I can rely on my coping skills/When faced with a problem I can usually identify several solutions/Usually, when I have a problem, I can think of a solution/I can usually handle any situation and any kind of problem I am faced with
Self-Esteem Scale	I am generally satisfied with myself/Sometimes I think I'm good for nothing/I feel that I have many qualities/I am able to do things as well as other people/I feel like I do not have much reason to be proud of myself/Sometimes I feel useless /I feel that I am as valuable a person as anyone else/I wish I had more respect for myself /I generally tend to think of myself as a loser/I have a positive attitude toward my person
General Attitudes and Beliefs Scale	The need for achievement, the need for approval, the need for comfort, the absolutist demand for justice, the overall assessment of others, overall assessment of self-worth, rationality, irrationality

Perception of Medical Career Specialty questionnaire	Financial importance, perception of opportunities for further specialization, challenging domain perception, perception of less stressful field, the importance of flexible schedule, important establishment in an urban environment, important research opportunity, didactic opportunity, short working hours, combination of hobby and job, comfortable lifestyle, the importance of the sense of vocation

The data were analyzed via GraphPad Prism 6.00 (GraphPad Software Inc.). For the comparative analysis, we used one-way ANOVA followed by post hoc Tukey's test for interactions between groups. With respect to career perception, we divided the students into 4 groups: surgery (students who might choose a surgical field after graduation), non-surgery (students who might choose a medical field, nonsurgical field after graduation), paraclinical (students who might choose a medical field with no patient contact after graduation), and N/A (students who did not decide about a specific field after graduation) and compared the main scores among them.

Considering the study year, we divided the students into two groups, namely, the preclinical group (students in the first two years of medical study) and the clinical group (students in the last four years of medical study), in accordance with the curricula of the general medicine studies, and compared various items between them. The data are expressed as the mean ± SEM. A two-sided P value <0.05 was considered statistically significant. For binary data, we used the chi-square test.

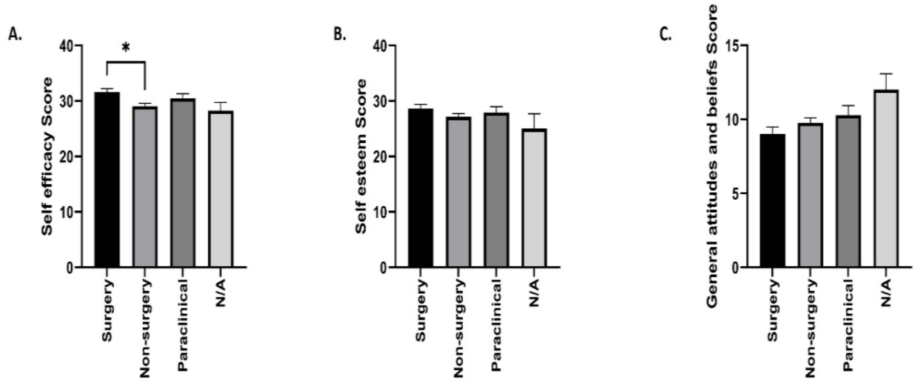
For the correlational data, we used a correlation matrix that included all the items independently. The Spearman correlation coefficient, r, was determined, considering the non-normal distribution of the group. We considered a two-sided P value <0.05 to indicate statistical significance for each correlation. We assigned r values under 0.4 to have negligible correlative effects. Finally, we excluded nonsignificant correlations.

RESULTS

Figure 1 shows the comparative analyses of self-esteem, self-efficacy and general attitudes and beliefs scores with respect to career perception. We observed relatively homogenous score values among the groups regardless of the career perception.

Considering the self-efficacy score, we observed the following mean values among the groups: surgery group vs. non-surgery group, 31.58±0.67 vs. 29.05±0.52 (p=0.018); paraclinical group, 30.48±0.82; and N/A group, 28.25±1.48, without any other statistically significant changes (Figure 1A). The mean self-esteem score with respect to career perception did not differ significantly among the groups: 28.6±0.79 in the surgery group, 27.16±0.56 in the non-surgery group, 27.9±1.08 in the paraclinical group, and 25±2.67 in the N/A group (Figure 1B). Furthermore, we revealed relative homogeneity among the groups in terms of the general attitudes and beliefs score: 9±0.49 in the surgery group, 9.77±0.33 in the non-surgery group, 10.29±0.65 in the paraclinical group, and 12±1.08 in the N/A group (Figure 1C).

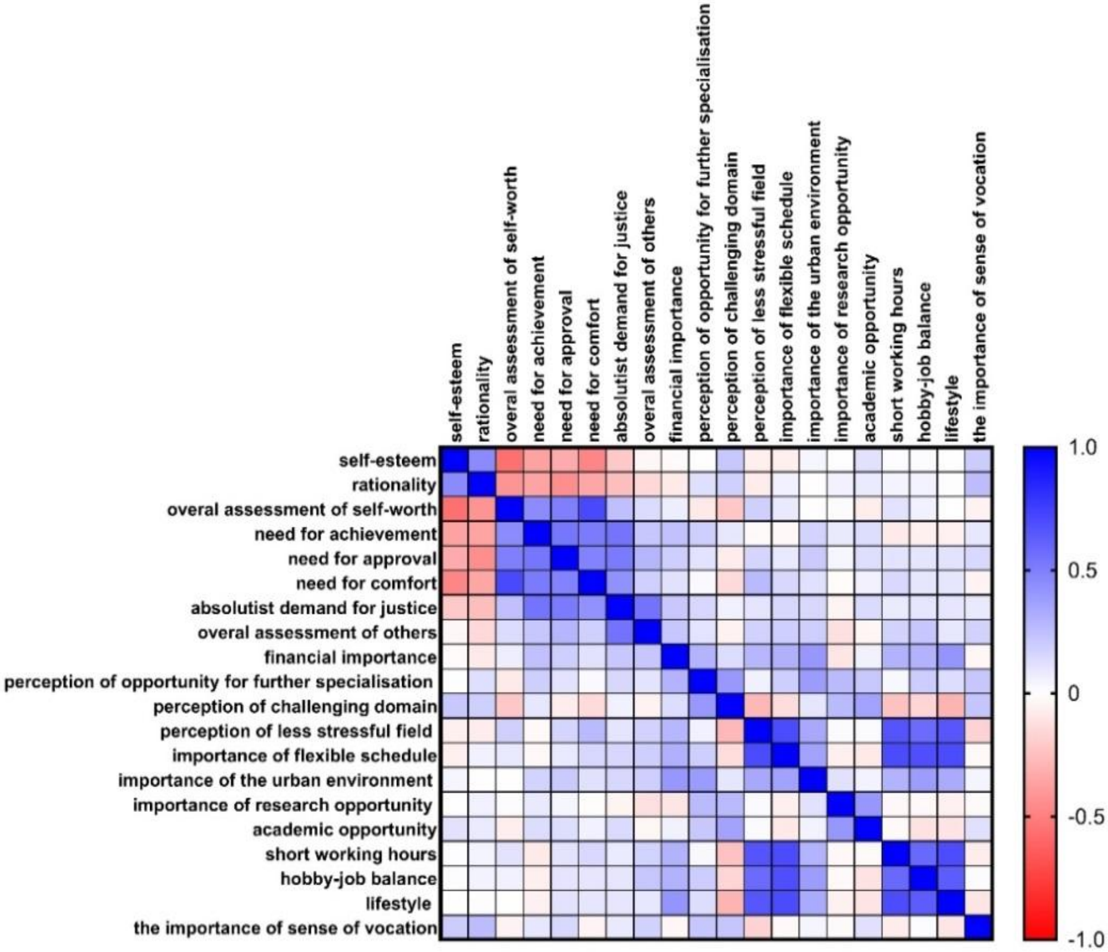
Figure 1: Comparative analysis of self-efficacy (A), self-esteem (B), and general attitudes and beliefs (C) scores between students who choose one of the following medical fields after graduation: surgical, non-surgical, paraclinical, or no option yet. The values are expressed as the means ± SEMs. * represents a p-value between 0.05 and 0.01



The correlations between self-esteem, self-efficacy, individual general beliefs and attitudes, and career-related perceptions among medical students are shown in Figure 2. The positive correlations are marked in blue, whereas the negative correlations are red.

Self-esteem correlated positively with rationality (r=0.51, p<0.001) and negatively with the overall assessment of self-worth (r=-0.56, p<0.001) and the need for comfort (r=-0.48, p<0.001). The rationality correlates negatively with the need for approval (r=-0.44, p<0.001). Additionally, the link between the overall assessment of self-worth and the need for comfort suggests a strong positive correlation (r=0.71, p<0.001). Moreover, the need for achievement correlates positively with the need for approval (r=0.53, p<0.001), comfort (r=0.51, p<0.001) and absolutist demand for justice (r=0.54, p<0.001). We also observed a positive correlation between the need for approval in student perception and the need for comfort (r=0.48, p<0.001) and absolutist demand for justice (r=0.51, p<0.001). The need for comfort also positively correlates with the absolutist demand for justice (r=0.42, p<0.001), which, further, correlates positively with the overall assessment of others (r=0.54, p<0.001). We revealed a weak positive correlation between financial importance and lifestyle (r=0.41, p<0.001) and between perceptions of opportunity for further specialization and perceptions of the challenging domain (r=0.41, p<0.001).

Figure 2: The main correlations between various items included in the 4 scores

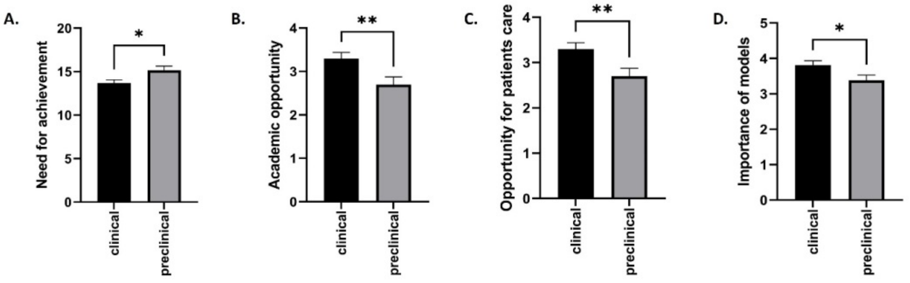


The perception of a less stressful field strongly correlates with the importance of a flexible schedule (r=0.7, p<0.001), short working hours (r=0.66, p<0.001), hobby-job balance (r=0.57, p<0.001), and lifestyle (r=0.65, p<0.001). Furthermore, we observed positive correlations between the importance of a flexible schedule and short working hours (r=0.7, p<0.001), hobby-job balance (0.68, p<0.001), and lifestyle (r=0.69, p<0.001), between short working hours and hobby-job balance (r=0.58, p<0.001) and lifestyle (r=0.69, p<0.001), and between hobby-job balance and lifestyle (r=0.63, p<0.001).

The comparative analyses between the years of study and the need for achievement, academic opportunity, opportunity for patient care, and importance of the models are shown in Figure 3.

Our study revealed a significantly greater score for need for achievement in the preclinical years than in the clinical years: 15.14±0.49 vs. 13.67±0.38 (p=0.03) (Fig. 3A). With respect to the academic opportunity, we observed a statistically significant increase in the perception score among the students from the clinical compared with those from the preclinical years: 3.29±0.14 vs. 2.69±0.17 (p=0.008) (Fig. 3B). Furthermore, the opportunity for patient care was better highlighted in the clinical group than in the preclinical group: 3.29±0.11 vs. 2.72±0.15 (p=0.008) (Fig. 3C). Finally, the importance of the models was greater for the students in the clinical years than for the students in the preclinical years: 3.8±0.12 vs. 3.38±0.15 (p=0.03) (Fig. 3D).

Figure 3: Comparative analysis between clinical and preclinical years of study and mean values of need for achievement (A), academic opportunity (B), opportunity for patient care (C), and importance of models (D). The values are expressed as the means ± SEM. The bars represent the SEM. * represents a p value between 0.05 and 0.01, ** represents a p value between 0.01 and 0.001



DISCUSSION

Modern management strategies in human resources in health care organizations should consider the sustainability potential of the providers, based on their self-efficacy, self-esteem, and general attitudes and beliefs perception. Thus, further organizational stability could be achieved and qualitative health care procedures guaranteed [15].

Our study reveals the role of occupational psychology among medical students, which better tailors the decisional tree for future medical subspecialties. Among the groups of students in different specializations, the analyzed variables, such as self-esteem, self-efficacy, general attitudes and beliefs, and career perceptions, are relatively homogeneous. Our results are in accordance with the literature. A recent study highlighted how self-esteem and self-efficacy are critical factors in career decision-making among medical students. Research indicated that medical students across various fields (surgery, general medicine, etc.) tend to show relatively uniform levels of self-efficacy and self-esteem, which are essential for their career maturity and decision-making abilities [16]. This is consistent with studies focusing on specialty identity and self-efficacy, where students from various medical disciplines demonstrated similar levels of career maturity and engagement [17].

Moreover, the importance of psychological factors such as self-esteem and career perception has been highlighted by a study examining flourishing and well-being. These studies revealed that regardless of their specialization, medical students benefit similarly from positive psychological constructs, which mediate their career decisions [18].

According to our results, the self-esteem of the medical students is closely related to rationality, suggesting that those with high self-esteem tend to think logically. Positive self-evaluations are associated with the need for justice, support, and approval, whereas irrationality is correlated with a desire for comfort and a critical evaluation of others. The need for absolute justice is linked to the importance of social status and a comfortable lifestyle, especially in the urban environment. Current research underscores the importance of self-esteem in rational decision-making and professional development in young adults, including medical students. For example, Harris and Orth highlighted in 2020 that high self-esteem is associated with rational behavior and an increased ability to face academic and professional challenges, which can positively influence students' career paths [19].

In terms of beliefs and attitudes, various data from the literature suggest that cognitive rigidity and irrational thinking can negatively affect professional adaptability. A study from David et al. discussed the negative impact of irrational beliefs on academic and professional performance, confirming observations that such beliefs can limit career success [20]. Career motivations, such as the need for specialization and the preference for a comfortable lifestyle, are critical to job satisfaction. Another study revealed that aligning career goals with personal values can increase motivation and career satisfaction [21].

Self-efficacy, defined as confidence in one's ability to achieve goals, plays a critical role in academic and professional success. Zajacova et al. identified that academic self-efficacy is a significant predictor of academic performance and the adjustment to university demands among young adults, highlighting the importance of this skill for medical students [22]. The results of our study show a significant correlation between interest in the specialty and the importance of a sense of duty. This suggests that students who show a strong interest in a particular medical specialty are motivated by a strong sense of duty to the profession and patients. Moreover, the importance of vocation and responsibility is related to the choice of medical specialties [23].

Global self-evaluation is a central construct in cognitive theory and is related to various forms of irrational demands, such as the need for absolutist justice and the need for approval, and research. Dryden and David suggest that absolutist demands and emotional needs are predictive factors for negative global self-evaluations [24]. Specifically, in our study, irrationality was correlated with the need for comfort, the absolutist demand for justice, and the global evaluation of others. Our results are in accordance with those of Ellis et al., in which irrationality might reflect a cognitive tendency to adopt extreme or unrealistic perspectives on the world and others [25]. This correlation suggests that when students face uncomfortable situations or perceive that justice is not respected, they may exhibit irrational tendencies, thus influencing their learning process and interpersonal relationships.

A statistically significant positive correlation between specialty interest and the importance of sense of duty suggests that students who are strongly interested in a particular specialty also have a well-developed sense of duty to the profession in that type of specialty and to their own patients, and these results are in accordance with the literature [26]. They noted that the perception of difficulty and complexity of a field can stimulate interest in in-depth specialization, as students seek to push their limits and acquire advanced skills. The importance of vocation and responsibility in choosing medical specialties integrates this psychosocial context [23].

Our study revealed that students who value teaching opportunities also appreciate the possibility of engaging in research activities. Our results are in accordance with those of Taylor et al., who revealed a link between the involvement of students in didactic activities and the research interest, considering it a natural extension of the academic learning [27].

Significant correlations between the year of study and the variables such as need for achievement, didactic opportunity, and opportunity for patient care, in our study, suggest a progressive development of the priorities of students and motivations as they progress through the degree program. These findings are consistent with another research showing that as students progress through medical education, they become more achievement-oriented and increasingly value role models of career success [28]. The importance of model perception with the progress through medical education could help further develop new sustainable management strategies in human resources.

Moreover, preclinical students often focus more on academic achievement and didactic learning. Some studies have demonstrated that role models significantly influence students' self-efficacy, particularly when these role models are seen as relatable and their success attainable [29,30]. Additionally, expectancy-value theory suggests that students who find mentors similar to themselves are more likely to value the associated career path, reinforcing the importance of mentorship in clinical education. This aligns with more recent research emphasizing the critical part that role models play in shaping the students' perceptions of their future careers [31]. Furthermore, achievement motivation and self-efficacy have been found to fluctuate on the basis of the type of mentorship and patient exposure students receive, which further highlights the transitional priorities from the preclinical to the clinical years [32]. These studies underscore the evolving nature of the motivations of the medical students and the influence of practical exposure and mentorship as they progress through their education.

The findings of this study emphasize the substantial influence of lifestyle factors on medical students' career preferences, which aligns with the literature. Many medical students today prioritize work–life balance, flexible schedules, and reduced working hours when selecting their specialties. A survey by Dorsey et al. revealed that the increasing importance of a controllable lifestyle has led to a shift in specialty preferences among U.S. medical students, with fewer students opting for time-demanding fields such as surgery and more favorable fields that offer a more predictable schedule [33]. Thus, in order to achieve stability of the human resource in the health care area, regardless of the medical sub-specialty, the medical organization should adhere to a predictable work program [34].

Furthermore, a study by Lambert and Holmboe revealed that medical students are increasingly focused on selecting specialties that allow them to maintain a balance between their professional and personal lives, contributing to their overall career satisfaction [35]. These findings mirror those of our study, where a flexible schedule and hobby-job balance were key factors for students aiming to pursue less stressful specialties.

Another study by Dyrbye et al. demonstrated that burnout among medical students and physicians is closely linked to lifestyle factors, with specialties offering better work–life balance associated with lower burnout rates [36]. These findings support our results, highlighting the need to consider lifestyle when guiding students in their career decision-making.

Finally, we observed an absence of a significant correlation between the importance of the sense of vocation and the other analyzed variables. This suggests that a sense of vocation, although considered an essential element in choosing a medical career, may function independently of other factors, such as teaching or research opportunities. This result is supported by the research of Newton and Grayson, who highlighted that vocation can be a strong intrinsic factor but is not necessarily related to external circumstances or other professional motivations [37].

Study limitations

Our research presents some limitations. Firstly, the lack of significant correlations does not necessarily indicate the absence of differences between groups but may be influenced by sample size. Secondly, the study was monocentric and did not consider the importance of intercultural variability among different societies. Finally, we did not perform a separate analysis of the enrolled international students.

CONCLUSION

Our study highlights the need for applying various occupational psychology tools for a more sustainable human resources in the health care system, considering the medical students as future providers. Further studies that explore other aspects or use alternative measurement methods are needed to confirm our results.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration for publication elsewhere. This research received no external funding.

Abstract: Sepsis remains a leading cause of morbidity and mortality worldwide, with certain high-risk populations—including elderly patients, neonates, immunocompromised individuals, those with chronic diseases, and pregnant women—experiencing worse outcomes. These groups exhibit distinct pathophysiological responses, which complicate diagnosis, treatment, and prognosis. Despite advancements in sepsis management, challenges persist in early risk stratification, individualized therapeutic strategies, and long-term recovery. Aim: This study aims to evaluate the impact of sepsis on high-risk populations, identify prognostic factors influencing clinical outcomes, and explore personalized treatment approaches to optimize patient management. Methodology: A systematic narrative review was conducted, following PRISMA guidelines, by analyzing peer-reviewed literature from 2015 to 2025. This study included the analysis of 80 scientific articles from eight international databases. Studies focusing on sepsis pathophysiology, microcirculatory dysfunction, diagnostic techniques, therapeutic interventions, and post-sepsis outcomes in high-risk populations were included. Results: Elderly patients demonstrated the highest sepsis-related mortality rates (>40%), while neonates and immunocompromised individuals exhibited delayed inflammatory responses, complicating diagnosis. Prognostic biomarkers such as IL-6 and IL-10 showed potential utility in these populations. Personalized fluid resuscitation, antimicrobial stewardship, and immune-modulating therapies were identified as critical to improving outcomes. Post-sepsis syndrome (PSS) was prevalent, particularly in survivors with chronic comorbidities and prolonged ICU stays. Conclusions: Optimizing sepsis management in high-risk populations requires a multidisciplinary, personalized approach, incorporating early biomarker-based diagnostics, precision-guided hemodynamic support, and tailored rehabilitation programs. Future research should focus on novel immunotherapies, antimicrobial resistance strategies, and long-term functional recovery in sepsis survivors.

Keywords: sepsis, microcirculatory dysfunction, prognostic biomarkers, post-sepsis syndrome, antimicrobial resistance

INTRODUCTION

Microcirculatory Alterations in Sepsis

Sepsis is a life-threatening condition characterized by a dysregulated host response to infection, leading to systemic inflammation, multi-organ dysfunction, and, in severe cases, death. One of the critical pathophysiological hallmarks of sepsis is microcirculatory dysfunction, which plays a pivotal role in tissue hypoxia and organ failure [1]. The microcirculation comprises small blood vessels, including arterioles, capillaries, and venules, responsible for oxygen delivery and metabolic exchange at the cellular level [2]. In sepsis, widespread endothelial activation, increased vascular permeability, and impaired autoregulation disrupt normal microvascular perfusion, exacerbating cellular distress and metabolic imbalance [3].

Microcirculatory alterations in sepsis are driven by complex interactions between inflammatory mediators, coagulation disturbances, and endothelial dysfunction. Inflammatory cytokines such as TNF-α, IL-6, and IL-1β induce endothelial cell activation, promoting leukocyte adhesion and microvascular thrombosis [4,5]. Additionally, nitric oxide (NO) dysregulation contributes to an imbalance between vasodilation and vasoconstriction, further impairing tissue perfusion [6].

From a diagnostic perspective, bedside techniques such as sublingual videomicroscopy and sidestream dark-field imaging (SDF) have emerged as valuable tools for assessing microcirculatory abnormalities in critically ill patients with sepsis [7]. These imaging modalities allow real-time visualization of capillary flow, providing essential insights into the extent of microvascular dysfunction and guiding therapeutic interventions. Advanced imaging approaches, including contrast-enhanced ultrasound (CEUS) and near-infrared spectroscopy (NIRS), offer additional perspectives on micro-circulatory heterogeneity and oxygenation deficits in septic patients [8,9].

Understanding microcirculatory impairments in sepsis is crucial for developing targeted therapeutic strategies aimed at restoring tissue perfusion and mitigating organ dysfunction [10]. Recent research has explored the potential benefits of fluid resuscitation strategies, vasoactive agents, and adjunctive therapies such as corticosteroids and endothelial-targeted interventions in optimizing microvascular function.

Fundamental Pathophysiological Mechanisms – Microcirculatory Dysfunction and Endothelial Abnormalities in Sepsis

The pathophysiological mechanisms underlying microcirculatory dysfunction in sepsis are complex and involve a cascade of inflammatory, coagulative, and endothelial disturbances that ultimately lead to impaired oxygen delivery and tissue hypoxia [11].

Microcirculatory impairment is a defining feature of sepsis, characterized by altered capillary perfusion, increased heterogeneity in blood flow, and endothelial dysfunction [12]. Unlike systemic hemodynamic failure, which is typically reflected in macrovascular changes (e.g., hypotension), sepsis-related microcirculatory alterations occur independently of blood pressure changes and directly contribute to organ failure [13].

Inflammation plays a central role in disrupting microcirculatory homeostasis. The excessive release of proinflammatory cytokines such as TNF-α, IL-6, and IL-1β leads to endothelial activation, increased vascular permeability, and leukocyte adhesion to the endothelium [14]. This inflammatory cascade results in endothelial swelling, capillary plugging by activated leukocytes, and microthrombi formation, all of which impede oxygen diffusion and exacerbate tissue hypoxia [15]. Additionally, dysregulated nitric oxide (NO) production contributes to vascular tone abnormalities, creating an imbalance between vasodilation and vasoconstriction that further disrupts blood flow distribution at the microvascular level [16].

From a structural perspective, capillary rarefaction and endothelial glycocalyx degradation are key pathological features of microcirculatory dysfunction in sepsis. The glycocalyx, a protective layer covering endothelial cells, plays a crucial role in vascular permeability and mechanotransduction [17]. In sepsis, glycocalyx breakdown due to enzymatic degradation (by heparanase and matrix metalloproteinases) results in increased vascular leakage, impaired shear stress sensing, and loss of anticoagulant properties, contributing to sepsis-induced coagulopathy (SIC) [18].

Endothelial dysfunction in sepsis is a result of direct cellular injury, oxidative stress, and immune activation. Endothelial cells, which normally maintain vascular homeostasis through the balanced release of vasoactive substances, become dysregulated, shifting towards a pro-inflammatory and pro-thrombotic phenotype [19].

One of the key mechanisms involved in endothelial dysfunction is increased expression of adhesion molecules such as ICAM-1, VCAM-1, and selectins, which facilitate leukocyte adhesion and transmigration into tissues, further amplifying inflammation [20]. This process leads to capillary plugging and increased diffusion distance for oxygen, creating a mismatch between oxygen delivery and cellular demand [21].

At the same time, mitochondrial dysfunction in endothelial cells exacerbates metabolic failure, reducing the ability of microvascular endothelial cells to regulate vascular tone and respond to local oxygen needs appropriately [22]. The resulting endothelial metabolic shutdown contributes to an irreversible cycle of hypoxia, organ dysfunction, and cellular apoptosis in severe sepsis cases [23].

Sepsis-induced coagulopathy (SIC) is a well-recognized phenomenon in which systemic inflammation disrupts the balance between coagulation and fibrinolysis, leading to widespread microthrombosis and perfusion defects [24]. The overactivation of the coagulation cascade is primarily driven by excessive tissue factor (TF) expression, leading to thrombin generation, platelet aggregation, and fibrin deposition within the microcirculation [25].

Additionally, antithrombotic mechanisms become suppressed due to reduced production of key anticoagulant proteins such as antithrombin, protein C, and thrombomodulin, further promoting a prothrombotic state [26]. The resulting microvascular thrombosis impairs capillary perfusion, leading to local ischemia, tissue necrosis, and multi-organ failure in severe septic shock cases [27].

Furthermore, fibrinolytic dysfunction exacerbates these complications. Sepsis induces the release of plasminogen activator inhibitor-1 (PAI-1), which suppresses fibrinolysis and prevents the clearance of microthrombi, further worsening microvascular obstruction

[28]. This shift towards a hypercoagulable state with impaired clot resolution represents a critical therapeutic target in sepsis management.

The long-term impact of microvascular dysfunction in sepsis extends beyond the acute phase of the disease. Persistent endothelial damage and capillary loss contribute to post-sepsis syndrome, characterized by prolonged inflammation, immune suppression, and residual organ dysfunction [29]. Chronic microvascular dysfunction has been linked to long-term cognitive impairment, cardiovascular complications, and persistent fatigue in sepsis survivors [30].

From a therapeutic standpoint, interventions targeting endothelial protection, micro-vascular flow optimization, and early coagulation modulation have shown promise in experimental and clinical studies [31]. Strategies such as glycocalyx preservation (e.g., fluid therapy with albumin, heparan sulfate analogs), endothelial stabilizing agents (e.g., steroids, angiopoietin modulators), and anticoagulant therapy in select patient populations are under investigation for their potential to mitigate sepsis-induced microvascular injury [32].

Prevalence of Microcirculatory Dysfunction in Sepsis

The prevalence of microcirculatory dysfunction in sepsis varies depending on disease severity, patient population, and the diagnostic techniques used. Studies using sublingual videomicroscopy and sidestream dark-field (SDF) imaging have shown that nearly 90% of patients with septic shock exhibit significant microvascular abnormalities, including reduced capillary density, increased flow heterogeneity, and impaired oxygen extraction [33,34]. Even in patients with less severe sepsis, microcirculatory alterations are observed in approximately 50–70% of cases, highlighting the early involvement of the microvasculature in disease progression [35].

The extent of microcirculatory dysfunction is closely linked to the severity of sepsis. In its early stages, microvascular perfusion changes may be subtle while overall hemodynamics remain stable. As sepsis advances to septic shock, severe capillary perfusion defects become more pronounced, leading to increased lactate levels, tissue hypoxia, and multi-organ failure [36].

Certain patient populations are particularly susceptible to profound microcirculatory disturbances. Elderly patients often experience more severe endothelial dysfunction due to age-related vascular changes and a diminished ability to compensate for inflammatory stress [37]. Patients with chronic diseases such as diabetes or chronic kidney disease face a heightened risk due to pre-existing endothelial dysfunction and oxidative stress, which exacerbate sepsis-induced microvascular damage [38]. Immunocompromised individuals, including cancer patients and transplant recipients, frequently exhibit atypical microcirculatory responses due to an altered inflammatory cascade, making early detection more challenging [39].

Microcirculatory dysfunction is significantly more prevalent in sepsis compared to other critical illnesses. In patients with non-septic shock, such as cardiogenic or hemorrhagic shock, global hemodynamic parameters may be compromised, but microvascular function remains relatively preserved in the early stages [40]. In contrast, sepsis induces early and widespread microvascular failure even when macrocirculatory parameters, such as blood pressure, appear normal [41].

In non-septic intensive care unit (ICU) patients, studies indicate that microcirculatory alterations affect only 10–30% of individuals, whereas in sepsis, this prevalence is three to five times higher [42]. This contrast highlights the unique impact of sepsis on the endothelium and microvascular network, making microcirculatory dysfunction a key prognostic indicator.

Special Categories of Patients with Sepsis

Sepsis represents a major challenge in medical practice, but certain categories of patients are at significantly higher risk of complications and mortality. These patients require tailored therapeutic approaches, as they have distinct physiological and immunological characteristics that influence their response to treatment and overall prognosis [43].

Older adults are particularly vulnerable to sepsis due to multiple physiological changes associated with aging. Their immune system undergoes a progressive decline, known as immunosenescence, which is characterised by a reduced ability to respond to infections and impaired production of pro-inflammatory cytokines [44]. Additionally, a state of chronic low-grade inflammation (inflamm-aging) contributes to dysfunctional immune responses, increasing the severity of sepsis.

From a cardiovascular perspective, elderly patients often exhibit increased vascular stiffness and reduced cardiac reserve, limiting their ability to compensate for septic shock [45]. Furthermore, frailty and sarcopenia negatively impact prognosis, increasing the risk of multiple organ failure.

The treatment of sepsis in elderly patients should be individualised, considering their increased risk of cardiovascular overload during fluid resuscitation and their predisposition to acute kidney injury. Close monitoring of haemodynamic status and careful adjustment of antimicrobial therapy based on renal function are essential to improving outcomes.

The presence of chronic diseases affects both the progression and management of sepsis, often complicating treatment strategies and patient outcomes.

Diabetic patients are more vulnerable to severe infections because persistent hyperglycaemia weakens neutrophil function and encourages the growth of resistant pathogens. Additionally, diabetes contributes to endothelial dysfunction, worsening the microcirculatory disturbances typical of sepsis [46].

Patients with chronic kidney disease experience a heightened risk of sepsis as uremia-induced immunosuppression weakens their immune response. The frequent use of vascular catheters further increases infection risks, while the accumulation of uraemic toxins disrupts immune function and slows antimicrobial clearance [47]. These factors make precise antibiotic dose adjustments essential, considering the patient's glomerular filtration rate.

Patients with chronic obstructive pulmonary disease are prone to respiratory sepsis because impaired mucociliary function and chronic airway inflammation promote recurrent infections. Prolonged corticosteroid use, a common treatment for COPD, can further suppress the immune system, making patients more susceptible to opportunistic infections [48].

Managing sepsis in patients with chronic conditions requires a careful approach that balances aggressive therapy with the risks posed by pre-existing diseases. Optimising antimicrobial therapy and fluid resuscitation plays a key role in preventing further deterioration of organ function [49].

Sepsis in children differs significantly from adult sepsis in terms of pathophysiology and clinical presentation. Neonates and infants have an immature immune system, making them more susceptible to severe bacterial and viral infections. Furthermore, infants have a limited ability to mount an effective inflammatory response, potentially delaying the diagnosis of sepsis [50].

Beyond immunological differences, children exhibit major variations in drug metabolism, necessitating careful adjustments in antibiotic and vasopressor dosing based on body weight and organ maturity [51].

Early recognition of sepsis is critical in paediatric patients, as hypotension—a hallmark of sepsis in adults—tends to appear late in children. Identifying early signs of impaired tissue perfusion is therefore essential for the timely initiation of treatment.

Immunosuppressed individuals face a significantly higher risk of severe sepsis and life-threatening complications, often with atypical clinical presentations that can delay diagnosis and treatment [52].

This group includes oncological patients, organ transplant recipients on immunosuppressive therapy, individuals with advanced HIV infection, and patients with autoimmune diseases undergoing biologic treatments. Due to a weakened immune response, sepsis in these patients is frequently caused by opportunistic pathogens, and the usual inflammatory signs may be absent. In cases of severe neutropenia, fever might not be present, making early detection more challenging [53].

Effective management relies on the prompt administration of broad-spectrum antibiotics, close monitoring of inflammatory markers, and immune support when necessary. Granulocyte-colony stimulating factor may be considered to enhance neutrophil recovery and improve outcomes in selected cases [54].

Pregnancy induces significant physiological changes that increase a woman's susceptibility to severe infections and septic complications. Increased placental blood flow and alterations in immune responses can influence both the progression of sepsis and the response to treatment [55].

Sepsis during pregnancy can have devastating consequences for both the mother and the fetus. Intrauterine infections, such as chorioamnionitis, may trigger preterm labour or result in fetal demise. Moreover, maternal hypotension and placental hypoperfusion can severely impact fetal development [56].

The management of sepsis in pregnancy must be prompt and aggressive, with rapid administration of antibiotics that are safe for the fetus and careful monitoring of maternal haemodynamic status. The timing and mode of delivery should be determined through a multidisciplinary approach, balancing maternal and fetal risks.

MATERIALS AND METHODS

This study employed a comprehensive approach to investigate the impact of chronic comorbidities on the progression and management of sepsis. A systematic narrative review methodology was chosen to integrate the structured rigor of a systematic review with a narrative synthesis approach, ensuring a nuanced analysis of a complex, multi-disciplinary topic. The review synthesizes existing literature on the interactions between sepsis and chronic conditions such as diabetes, chronic kidney disease (CKD), chronic obstructive pulmonary disease (COPD), and immunosuppressive states, emphasizing clinical implications and future research directions.

The analysis focused on three key aspects:

Pathophysiological mechanisms underlying increased susceptibility to sepsis in patients with diabetes, CKD, COPD, and immunosuppression, highlighting immune dysfunction, endothelial damage, and microbiome alterations.

Impact of chronic diseases on sepsis outcomes, including prolonged hospitalization, increased mortality risk, and the need for individualized therapeutic strategies.

Optimization of sepsis management in these high-risk populations, exploring antimicrobial stewardship, fluid resuscitation strategies, immunomodulatory therapies, and personalized treatment approaches based on disease-specific factors.

A key question that shaped the direction of this review was: How do chronic comorbidities influence the pathophysiology, clinical presentation, and management of sepsis, and what strategies can optimize patient outcomes in these high-risk populations?

To ensure a systematic synthesis of findings, studies were selected based on predefined inclusion criteria, prioritizing clinical trials, observational research, and meta-analyses that explored sepsis in patients with chronic comorbidities. A comparative evaluation of treatment strategies was conducted, examining the effectiveness and safety of current therapeutic approaches while identifying gaps in knowledge and areas requiring further investigation.

Approach to Identifying Relevant Articles

A systematic literature search was performed across multiple academic databases, including PubMed, Scopus, Web of Science, Elsevier, Springer, Wiley Online Library, MDPI, and Frontiers, to investigate the role of microcirculatory dysfunction in sepsis. The search process adhered to PRISMA guidelines, employing Boolean operators (AND, OR) to enhance search precision and optimize the identification of relevant studies on microvascular changes associated with sepsis.

Key search terms included: "microcirculatory dysfunction in sepsis" (17,100 results), "sepsis-induced endothelial dysfunction" (17,800 results), "capillary perfusion in septic shock" (16,700 results), "microvascular alterations and organ failure" (18,300 results), and "sepsis-associated mitochondrial dysfunction" (10,800 results).

Structured search strings were applied to maximize relevance and retrieve high-quality studies, such as: "(microcirculatory dysfunction OR endothelial dysfunction) AND (sepsis OR septic shock) AND (capillary perfusion OR mitochondrial dysfunction)."

To ensure the inclusion of the most relevant and up-to-date studies, several selection filters were applied. The search was restricted to publications from 2015 to 2025, allowing for the incorporation of both recent developments and foundational research that contribute to the understanding of microvascular dysfunction in sepsis. Only full-text articles available in English were considered to ensure accessibility to studies with broad international relevance.

The review focused exclusively on peer-reviewed literature, including clinical trials, systematic reviews, and meta-analyses. Priority was given to review articles offering a comprehensive synthesis of current knowledge, while clinical studies were evaluated for their insights into the relationships between microvascular dysfunction, disease progression, and treatment outcomes.

Search queries were tailored for each database to account for variations in indexing and search functionalities. Beyond standard database searches, citation tracking and reference analysis of key studies were conducted to identify additional relevant research that may not have been captured in the initial search. This method helped enhance the dataset by incorporating essential studies that might have been overlooked through automated search strategies.

Eligibility Criteria for Study Selection

Inclusion Criteria

The selected studies needed to address the challenges and treatment approaches for sepsis in high-risk patient groups. Included publications were required to provide relevant information on these aspects:

Pathophysiological mechanisms, such as immune dysregulation, endothelial dysfunction, and metabolic alterations in neonates, elderly patients, immunocompromised individuals, and those with chronic diseases.

Diagnostic and monitoring strategies, including biomarkers, advanced hemodynamic assessment tools, and molecular diagnostics for early detection and risk stratification.

Therapeutic approaches, addressing personalized treatment strategies, the role of immune modulation, tailored fluid resuscitation, and organ-support therapies such as renal replacement therapy and extracorporeal membrane oxygenation (ECMO).

The review incorporated original research, systematic reviews, meta-analyses, and clinical studies published in peer-reviewed, indexed journals to ensure the selection of high-quality, reliable sources.

Exclusion Criteria

The following types of studies were not included in the review:

Research that did not adhere to PRISMA guidelines, as standardized reporting is crucial for ensuring methodological reliability.

Case reports that lacked generalizability or did not provide adequate data on sepsis treatment in high-risk patient populations.

Studies that focused only on general aspects of sepsis without addressing the specific challenges faced by neonates, elderly individuals, immunocompromised patients, or those with chronic illnesses.

Articles that were not based on original research or were published in non-peer-reviewed sources were excluded, ensuring that only high-quality, evidence-based studies were considered.

Selection Process

A structured approach was used to evaluate all identified articles based on predefined inclusion and exclusion criteria, ensuring the selection of high-quality, methodologically sound studies relevant to the research objectives. The PRISMA framework was implemented throughout the process to maintain transparency and consistency in study identification. The final selection offers a comprehensive analysis of sepsis patho-physiology, diagnostic methods, and treatment strategies in vulnerable patient populations.

The selection process was carried out in two main stages. In the initial stage, titles and abstracts were screened to determine relevance, prioritizing studies that focused on sepsis in neonates, elderly individuals, immunocompromised patients, and those with chronic conditions. Studies that did not specifically address these populations or lacked original research data were excluded at this point.

During the second stage, a full-text review was conducted on the remaining articles. Preference was given to studies that examined the relationship between sepsis severity, microvascular dysfunction, immune response alterations, and organ failure. Additionally, research discussing tailored treatment approaches—such as immune modulation, hemodynamic stabilization, and organ-support therapies—was prioritized.

To ensure the credibility and reliability of findings, all selected studies underwent a rigorous quality assessment to confirm adherence to PRISMA guidelines and alignment with the research scope. This approach helped minimize potential biases and strengthened the validity of the conclusions drawn.

Despite efforts to create a comprehensive selection, certain limitations must be acknowledged. The exclusion of grey literature may have led to the omission of valuable studies not indexed in major academic databases. Restricting the review to English-language publications may have excluded relevant research available in other languages. Additionally, limiting the search to specific databases may have overlooked studies published in other sources. Lastly, the decision to focus on research published between 2015 and 2025 may have resulted in the exclusion of older foundational studies that could provide historical insights into sepsis mechanisms and treatment advancements.

RESULTS

Overview of Selected Studies

To ensure transparency and traceability in the selection process, a PRISMA diagram has been included in the material, illustrating the number of studies identified and filtered at each stage of the analysis. This diagram initially presents the total number of articles retrieved through the search, followed by the number of those excluded after reviewing titles and abstracts, and finally, the number of studies selected for in-depth analysis. Additionally, the reasons for excluding certain articles are specified, providing clarity regarding the decisions made during the selection process.

The use of the PRISMA diagram is essential for maintaining transparency, as it allows readers to understand the decision-making process behind article selection and ensures compliance with the criteria established at the outset of the review [57,58].

The PRISMA flow diagram in Figure 1 outlines the selection process for studies examining microcirculatory dysfunction and sepsis management in vulnerable patient populations. A systematic search was performed across eight major databases, yielding a total of 80,700 results.

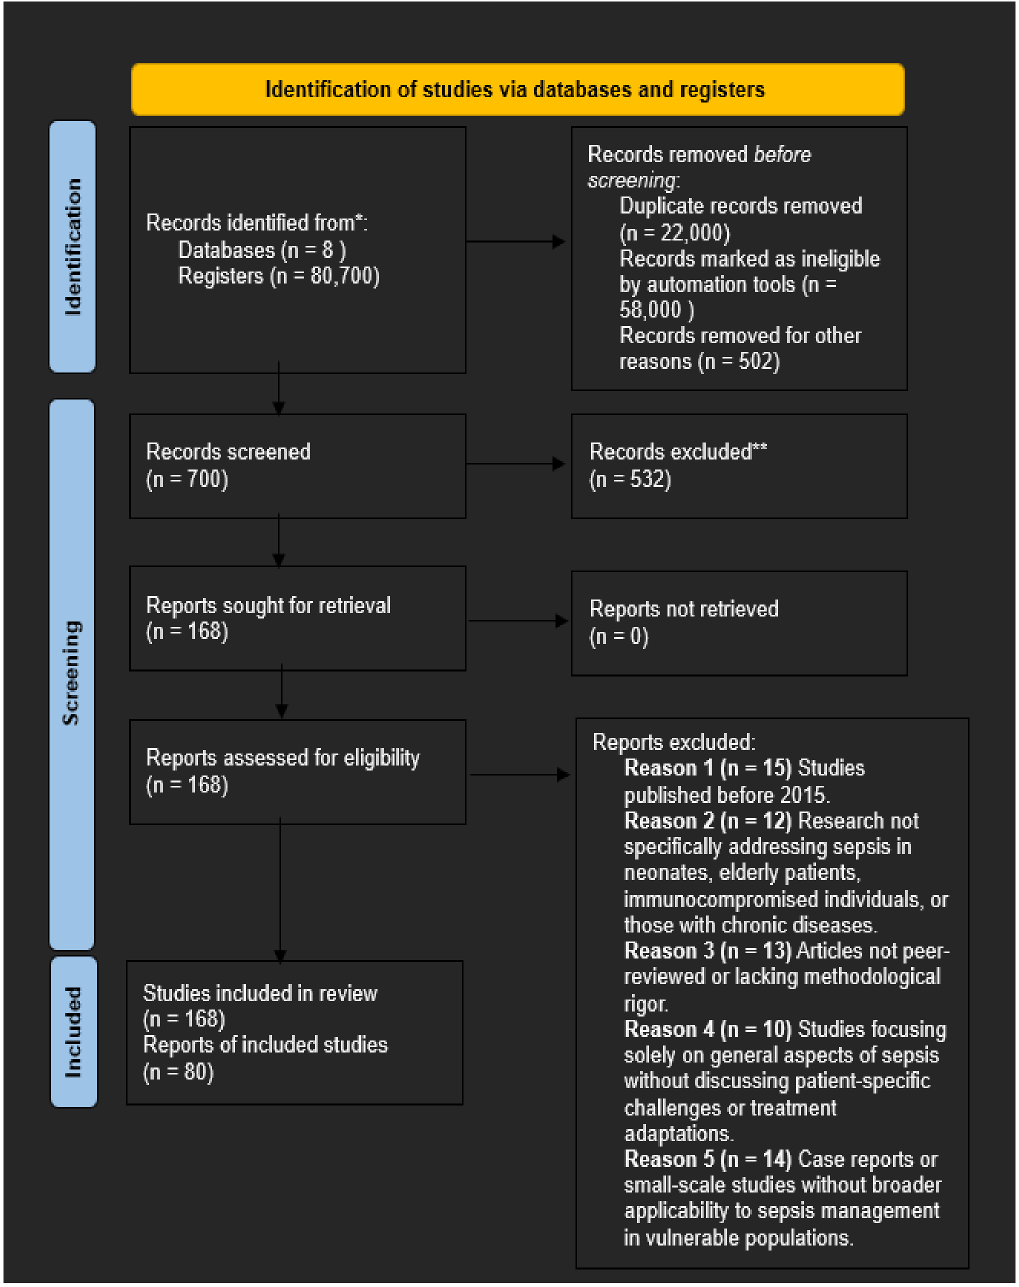
Following the removal of duplicate records (22,000) and studies excluded due to lack of relevance, incomplete data, or methodological limitations (502), a total of 700 articles remained for screening.

During the initial screening phase, 532 records were excluded based on predefined criteria, primarily for not specifically addressing sepsis in neonates, elderly individuals, immunocompromised patients, or those with chronic diseases. In the first review phase, 168 studies were assessed for eligibility, with articles evaluated for their relevance to sepsis pathophysiology, diagnostic tools, and treatment strategies.

In the second phase, a more detailed evaluation was conducted, applying stricter inclusion criteria related to immune dysregulation, microvascular dysfunction, and patient-specific therapeutic approaches. Studies that focused solely on general aspects of sepsis without addressing unique challenges faced by high-risk patient groups were excluded.

The final selection included 80 studies, covering a wide range of topics, including the pathophysiological mechanisms of sepsis, personalized treatment strategies, and emerging diagnostic technologies. These studies, published between 2015 and 2025, provide valuable insights into optimizing sepsis management in vulnerable populations.

Figure 1: PRISMA Flow Diagram of articles related to Microcirculatory Dysfunction and Sepsis Management in Vulnerable Patient Populations



Identification of studies via databases and registers
Identification
Screening
Included
Records identified from*: Databases (n = 8) Registers (n = 80,700)
Records removed *before screening*: Duplicate records removed (n = 22,000) Records marked as ineligible by automation tools (n = 58,000) Records removed for other reasons (n = 502)
Records screened (n = 700)
Records excluded** (n = 532)
Reports sought for retrieval (n = 168)
Reports not retrieved (n = 0)
Reports assessed for eligibility (n = 168)
Reports excluded:
Reason 1 (n = 15) Studies published before 2015.
Reason 2 (n = 12) Research not specifically addressing sepsis in neonates, elderly patients, immunocompromised individuals, or those with chronic diseases.
Reason 3 (n = 13) Articles not peer-reviewed or lacking methodological rigor.
Reason 4 (n = 10) Studies focusing solely on general aspects of sepsis without discussing patient-specific challenges or treatment adaptations.
Reason 5 (n = 14) Case reports or small-scale studies without broader applicability to sepsis management in vulnerable populations.
Studies included in review (n = 168) Reports of included studies (n = 80)

This systematic review was conducted following the PRISMA 2020 guidelines. The PRISMA checklist and flow diagram are provided as supplementary materials.

This methodology enabled a comprehensive analysis of the specialized literature, synthesizing key findings on microcirculatory dysfunction and sepsis management in vulnerable patient populations. By incorporating data from multiple disciplines, this approach provided a well-rounded understanding of sepsis pathophysiology, diagnostic innovations, and personalized treatment strategies.

The studies included in the results section strictly followed the predefined inclusion criteria, ensuring the selection of high-quality and relevant research aligned with the core objectives of this review. These studies were systematically analyzed and synthesized to explore the relationship between microvascular alterations, immune dysregulation, and patient-specific therapeutic approaches, offering objective data and clinically significant insights to enhance sepsis management in high-risk groups.

Sepsis in High-Risk Patient Populations: Unique Challenges and Management Strategies

Patients at increased risk of sepsis belong to special categories, each with specific physiological, immunological, and clinical characteristics that significantly influence disease progression and response to treatment. In these groups, sepsis can progress rapidly, present with atypical symptoms, and have a more severe prognosis, requiring personalized management and close monitoring (Table 1).

Table 1: Categories of Patients at Increased Risk of Sepsis and Their Specific Characteristics

Patient Category	Specific Characteristics	References
Elderly Patients	- Immunosenescence: weakened immune response - Blunted inflammatory response (atypical symptoms) - Compromised cardiovascular and renal function - Increased risk of multi-organ dysfunction	[59], [60]
Patients with Chronic Comorbidities	- Impaired immunity due to preexisting conditions (diabetes, kidney disease, COPD, heart failure) - Increased oxidative stress and chronic inflammation - Risk of hemodynamic imbalances and fluid overload	[61]
Pediatric Patients	- Immature immune system - Increased risk of bacteremia and multi-organ dysfunction - Different drug metabolism (requires careful dose adjustment) - Nonspecific symptoms (lethargy, hypothermia, feeding difficulties)	[62], [63]
Immunocompromised Patients	- Weakened inflammatory response (atypical symptoms) - Increased susceptibility to opportunistic infections - Requires aggressive antibiotic therapy and intensive monitoring	[64], [65]
Pregnant Women	- Physiological changes increase infection susceptibility and excessive inflammation - Early signs may be masked by cardiovascular adaptations - Specific risks: chorioamnionitis, postpartum endometritis - Therapy must be carefully selected to ensure fetal safety	[66], [67]

As we can see in Table 1, elderly patients face a range of physiological and immunological changes that increase their vulnerability to sepsis. With aging, the immune system undergoes immunosenescence, characterized by a weakened innate and adaptive immune response. This leads to a reduced ability to combat infections and a delayed activation of defense mechanisms [59]. Additionally, the inflammatory response may be blunted, meaning classic symptoms of sepsis, such as fever and tachycardia, may be absent or less pronounced. Cardiovascular and renal functions are often compromised in elderly individuals, making hemodynamic balance and fluid management more challenging. Their overall frailty, combined with a higher risk of multi-organ dysfunction, necessitates a carefully tailored therapeutic approach to prevent rapid deterioration and severe complications [60].

Patients with chronic comorbidities represent another high-risk group, as preexisting conditions directly impact infection response and the body's ability to maintain homeostasis during sepsis. Diabetes mellitus, for example, impairs immune function by increasing oxidative stress, altering neutrophil function, and reducing phagocytic capacity, making severe infections and associated complications more likely [61]. Chronic kidney disease leads to the accumulation of uremic toxins that suppress immune function and increase susceptibility to opportunistic infections. Additionally, patients with chronic obstructive pulmonary disease or heart failure exhibit persistent inflammatory states and limited functional reserves, causing sepsis to exacerbate these conditions rapidly. For these patients, treatment strategies must balance infection control, organ protection, and the prevention of adverse effects, such as fluid overload from aggressive resuscitation.

Pediatric patients exhibit significant physiological and immunological differences compared to adults, affecting both the presentation and management of sepsis. The immune system of neonates and infants is underdeveloped, resulting in a reduced ability to mount an effective response against infections, which increases the risk of bacteremia and multi-organ dysfunction [62]. Additionally, drug metabolism differs in children, requiring careful dose adjustments for antibiotics and other therapies based on body weight and organ maturity. Clinical signs of sepsis in this group are often non-specific, including lethargy, respiratory distress, hypothermia, or feeding difficulties, making early diagnosis challenging. Close monitoring and rapid intervention are crucial to preventing severe complications and reducing mortality in pediatric sepsis [63].

Immunocompromised patients, including those with cancer, autoimmune diseases, or those undergoing immunosuppressive therapy, are highly vulnerable to sepsis due to an impaired immune system that cannot effectively control infections. The absence of a robust inflammatory response allows infections to spread quickly, and classic sepsis symptoms such as fever and leukocytosis may be absent, leading to delayed diagnosis [64]. These patients are also prone to opportunistic infections caused by pathogens that are typically non-threatening to immunocompetent individuals, complicating the choice of antimicrobial therapy. Sepsis management in immunocompromised patients requires an aggressive approach, including the rapid administration of broad-spectrum antibi-otics, intensive monitoring, and, in some cases, adjunctive therapies to support immune function [65].

Pregnant women represent a unique high-risk category for sepsis, as physiological changes during pregnancy can increase both infection susceptibility and exaggerated inflammatory responses. The immune system undergoes adaptations to tolerate the presence of the fetus, potentially reducing the ability to fight off infections effectively [66]. Simultaneously, increased plasma volume and cardiac output alter the body's response to infection and can mask early signs of sepsis. Obstetric infections, such as chorioamnionitis and postpartum endometritis, are common causes of sepsis during pregnancy and can have severe consequences for both the mother and the fetus. Treating sepsis in pregnant women requires careful consideration of fetal safety, necessitating the selection of appropriate antibiotics and close hemodynamic monitoring to prevent maternal and fetal complications [67].

Each of these special patient categories requires a personalized approach to sepsis management, tailored to their unique physiological and immunological characteristics. Early diagnosis, intensive monitoring, and prompt therapeutic interventions are essential to improving outcomes and reducing mortality in these vulnerable populations.

Tailored Therapeutic Approaches for Special Patient Populations in Sepsis

Managing sepsis in high-risk patient populations requires a personalized therapeutic approach that considers age, comorbidities, immune status, and physiological differences. Standard treatment protocols may not be fully applicable to these groups, necessitating dose adjustments, targeted antimicrobial strategies, and specialized supportive interventions to optimize outcomes while minimizing complications.

Table 2 presents the key therapeutic considerations for each of these high-risk patient groups, highlighting the necessary adjustments in sepsis management to optimize clinical outcomes and reduce complications.

Table 2: Tailored Therapeutic Approaches for Special Patient Populations in Sepsis

Patient Category	Key Therapeutic Considerations	References
Elderly Patients	- Adjust antibiotic dosages due to reduced renal and hepatic function - Lower doses or extended intervals for renally excreted antibiotics (e.g., aminoglycosides, vancomycin) to prevent nephrotoxicity - Monitor for fluid overload and hypotension with advanced hemodynamic tools (e.g., echocardiography)	[68], [69], [72]
Pediatric Patients	- Use weight-based dosing due to immature liver enzymes and different drug metabolism - Close monitoring of oxygenation, perfusion, and fluid balance - Early noninvasive ventilation (e.g., high-flow nasal cannula) to prevent respiratory failure - Adjust antibiotic regimens based on age-specific pharmacokinetics	[73], [74]
Patients with Chronic Comorbidities	- Modify medication regimens to prevent interactions (e.g., fluid overload in heart failure) - Adjust diabetes management to avoid sepsis-induced hyperglycemia - Consider early renal replacement therapy in patients with kidney disease - Balance infection control with organ protection strategies	[71], [75]
Immunocompromised Patients	- Use prolonged or higher-dose antibiotic courses if needed, balancing toxicity risks - Consider antifungal and antiviral coverage for broader protection - Utilize immunotherapies such as G-CSF for neutropenic patients - Monitor for opportunistic infections and tailor treatment accordingly	[70], [76], [79], [80]
Pregnant Women	- Select antibiotics carefully to avoid teratogenic risks (prefer beta-lactams, macrolides, cephalosporins) - Adjust dosages based on increased plasma volume and altered metabolism - Monitor fetal well-being and placental perfusion in maternal hypotension - Involve obstetric and neonatal specialists for optimal maternal-fetal outcomes	[83], [84], [85], [86], [87]

According to Table 2, antibiotic and medication dosages must be carefully adapted based on age, underlying conditions, and overall patient status. In elderly patients, reduced renal and hepatic function can significantly alter drug metabolism and clearance, increasing the risk of toxicity [68]. Lower doses or extended dosing intervals may be required for renally excreted antibiotics such as aminoglycosides and vancomycin to prevent accumulation and nephrotoxicity [69]. Pediatric patients have immature liver enzyme systems and differing body compositions, necessitating weight-based dosing and close monitoring to ensure therapeutic efficacy while avoiding adverse effects. In immunocompromised individuals, higher or prolonged antibiotic courses may be required due to impaired immune clearance of pathogens, but this must be balanced against the risk of toxicity and resistance [70]. Patients with chronic diseases, such as diabetes or heart failure, may require modifications in medication regimens to avoid interactions or worsening of underlying conditions, such as fluid overload with aggressive intravenous hydration [71].

Supportive interventions play a critical role in managing sepsis in these vulnerable populations. Elderly patients often have diminished cardiovascular reserve, making them prone to hypotension and fluid overload, requiring careful hemodynamic monitoring using advanced tools such as echocardiography or dynamic fluid responsiveness tests [72]. Pediatric patients, particularly neonates, have immature cardiovascular and respiratory systems, necessitating closer monitoring of oxygenation, perfusion, and fluid balance [73]. In critically ill patients with underlying respiratory diseases such as chronic obstructive pulmonary disease or in neonates with underdeveloped lung function, early implementation of noninvasive ventilation or high-flow nasal cannula therapy can help prevent respiratory deterioration [74]. Patients with renal impairment may require early initiation of renal replacement therapy to prevent worsening metabolic derangements and fluid overload [75].

Targeted antimicrobial therapy is essential to optimizing treatment outcomes while minimizing the risk of antibiotic resistance, particularly in patients with recurrent sepsis [76]. Broad-spectrum antibiotics should be initiated promptly but de-escalated based on culture results and antimicrobial susceptibility testing to avoid unnecessary prolonged exposure to broad-spectrum agents [77]. In patients with frequent hospitalizations or prior antibiotic exposure, local resistance patterns should guide empirical therapy to ensure adequate pathogen coverage [78]. Immunocompromised patients, such as those undergoing chemotherapy or organ transplant recipients, are at higher risk for fungal or viral infections in addition to bacterial sepsis, necessitating a broader diagnostic approach and potential inclusion of antifungal or antiviral agents in their treatment regimen [79].

Immunotherapy has emerged as a potential adjunct in managing sepsis, particularly in immunocompromised individuals. Strategies such as the administration of granulocyte colony-stimulating factor (G-CSF) can enhance neutrophil function in patients with chemotherapy-induced neutropenia, reducing the risk of severe infections [80]. Intravenous immunoglobulins (IVIG) may be beneficial in certain septic patients with antibody deficiencies, such as those with primary immunodeficiencies or hypogammaglobulinemia secondary to chronic diseases [81]. Additionally, emerging therapies targeting immune modulation, such as checkpoint inhibitors and cytokine blockade, are being explored to balance excessive inflammatory responses and prevent immune paralysis in sepsis [82]. However, these approaches require further clinical validation to determine their efficacy and safety across different patient populations.

Special considerations are necessary when treating sepsis in pregnant women to minimize risks to both the mother and fetus. Physiological changes in pregnancy, including increased plasma volume, altered renal clearance, and changes in drug metabolism, require careful selection and dosing of medications [83]. Certain antibiotics, such as tetracyclines and fluoroquinolones, should be avoided due to potential teratogenic effects or adverse fetal outcomes [84]. Beta-lactams, macrolides, and selected cephalosporins are generally considered safe and are preferred when treating infections in pregnancy [85]. Management of sepsis in pregnant patients also involves close fetal monitoring, particularly in cases of maternal hypotension, as reduced placental perfusion can lead to fetal distress [86]. Early involvement of obstetric and neonatal specialists is crucial to ensuring optimal maternal and fetal outcomes, particularly in cases requiring preterm delivery due to worsening maternal condition [87].

A tailored therapeutic approach is essential in managing sepsis in high-risk populations, as a one-size-fits-all strategy may not be effective or safe. Personalized dosing regimens, targeted antimicrobial selection, intensive supportive care, and emerging immunomodulatory therapies must be carefully integrated into treatment plans to improve survival and reduce complications in these vulnerable patient groups.

Outcomes and Prognostic Factors in Sepsis Among High-Risk Patient Populations

The prognosis of sepsis varies significantly among different patient populations, with special categories such as the elderly, pediatric patients, immunocompromised individuals, those with chronic diseases, and pregnant women facing distinct challenges that influence survival rates, recurrence risk, and long-term health outcomes. The interaction between individual patient characteristics, severity of illness, and therapeutic interventions plays a crucial role in determining overall outcomes.

Mortality and morbidity rates in sepsis differ across patient groups, with elderly individuals exhibiting the highest case fatality rates due to pre-existing frailty, immune senescence, and a diminished physiological reserve. Studies indicate that sepsis-related mortality in elderly patients can exceed 40%, particularly in those with multi-organ dysfunction or underlying cardiovascular disease [88]. Pediatric patients generally have lower mortality rates due to their greater physiological resilience and the ability to recover from severe infections when treated promptly [89]. However, neonates and premature infants remain highly vulnerable, with significantly higher sepsis-related mortality due to their immature immune systems and increased susceptibility to bloodstream infections [90]. Immunocompromised individuals, including cancer patients, transplant recipients, and those undergoing immunosuppressive therapy, also face elevated mortality risks, as their inability to mount an adequate immune response allows infections to progress more aggressively [91]. Patients with chronic diseases such as diabetes, chronic kidney disease, and chronic obstructive pulmonary disease experience worse outcomes due to baseline organ dysfunction, which limits their ability to compensate for sepsis-induced metabolic and inflammatory disturbances [92]. Pregnant women with sepsis generally have lower mortality rates compared to other high-risk groups, but severe maternal sepsis remains a leading cause of maternal morbidity and can result in adverse fetal outcomes, including preterm birth and stillbirth [93].

The success of treatment and the likelihood of sepsis recurrence depend on multiple factors, including early diagnosis, appropriate antimicrobial therapy, hemodynamic stabilization, and organ support. Patients in high-risk categories often require more aggressive and prolonged interventions, yet they may also experience higher rates of treatment failure. In elderly patients, delayed recognition of sepsis due to atypical presentations contributes to increased mortality, and even those who survive the acute phase frequently develop post-sepsis complications such as cognitive decline and functional impairment [94]. Pediatric patients, despite their potential for recovery, may experience long-term immunological and developmental consequences following severe sepsis. Immunocompromised individuals often require extended antimicrobial treatment due to persistent infection risks, but this increases their susceptibility to antimicrobial resistance and recurrent sepsis episodes [95]. Patients with chronic diseases frequently experience sepsis relapses, particularly when their underlying conditions are poorly controlled, leading to recurrent hospitalizations and a progressive decline in overall health status [96].

Prognostic factors vary based on patient category and the therapeutic approach used. In elderly patients, markers of frailty, pre-existing comorbidities, and the presence of multi-organ dysfunction strongly predict poor outcomes. In pediatric sepsis, factors such as gestational age, birth weight, and early initiation of antibiotics influence survival rates [97]. Immunocompromised patients with profound neutropenia or severe lymphopenia are at the highest risk of mortality, particularly when infections are caused by multidrug-resistant organisms or opportunistic pathogens [98]. The effectiveness of immunotherapy, such as granulocyte colony-stimulating factor (G-CSF) or intravenous immunoglobulin (IVIG), in improving survival in these patients remains an area of ongoing research. In patients with chronic diseases, glycemic control in diabetics, renal function stability in those with kidney disease, and optimal management of pulmonary disease play critical roles in determining outcomes [99]. Pregnant women with sepsis have better prognoses when infections are detected early and treated promptly, but complications such as septic shock, disseminated intravascular coagulation, and fetal distress significantly worsen both maternal and fetal outcomes [100,101].

The long-term impact of sepsis on quality of life has become an increasingly important topic of discussion, particularly with the recognition of post-sepsis syndrome (PSS), a condition characterized by persistent physical, cognitive, and psychological impairments following recovery from sepsis [102]. Many sepsis survivors experience chronic fatigue, muscle weakness, neuropathy, and reduced exercise tolerance, which significantly impact their ability to perform daily activities [103]. Cognitive dysfunction, including memory impairment and difficulty concentrating, is particularly common in elderly patients and those who require prolonged intensive care unit (ICU) stays [104]. Anxiety, depression, and post-traumatic stress disorder (PTSD) are frequently reported, further diminishing quality of life [105]. Pediatric patients who survive sepsis may experience developmental delays and long-term neurocognitive impairments, especially if they suffered from hypoxia or severe inflammation during the acute phase [106]. Immunocompromised patients often face ongoing infection risks and require long-term prophylactic antimicrobial therapy, increasing their burden of care. Individuals with chronic diseases who survive sepsis often experience accelerated disease progression, leading to increased dependence on healthcare resources [107]. Pregnant women who recover from sepsis may face complications such as placental insufficiency, preterm labor, or long-term cardiovascular effects, emphasizing the need for close postpartum monitoring [108].

The impact of long-term sepsis management on patient health and functionality underscores the importance of comprehensive post-discharge care. Early rehabilitation programs, including physical therapy and cognitive training, can help mitigate some of the adverse effects of post-sepsis syndrome [109]. Ongoing monitoring for secondary infections, organ dysfunction, and psychological distress is essential to improving the long-term well-being of sepsis survivors. Targeted interventions, such as personalized nutrition plans, immune-modulating therapies, and infection prevention strategies, may help reduce the risk of recurrent sepsis and promote a better quality of life for high-risk patients [110].

The prognosis and long-term outcomes of sepsis vary widely depending on patient characteristics, timely intervention, and post-sepsis care. While advances in early recognition and targeted therapies have improved survival rates, the high burden of post-sepsis complications highlights the need for continued research and multidisciplinary approaches to optimize long-term recovery in vulnerable populations.

Microcirculatory Dysfunction in Sepsis and Its Clinical Implications

Microcirculatory dysfunction plays a critical role in the progression and severity of sepsis, significantly influencing patient outcomes. Various diagnostic techniques are employed to assess alterations in microvascular perfusion, endothelial integrity, and oxygen delivery at the tissue level. Sublingual video microscopy, using techniques such as sidestream dark field (SDF) imaging, allows for direct visualization of capillary flow abnormalities [111]. Near-infrared spectroscopy (NIRS) is utilized to evaluate tissue oxygenation, while biomarkers such as lactate levels and endothelial activation markers provide additional insights into microvascular impairment [112].

The characteristics of microcirculatory dysfunction in sepsis differ significantly from those observed in other critical illnesses. Septic patients frequently exhibit extensive capillary heterogeneity, increased leukocyte-endothelial interactions, and impaired oxygen extraction, even when macrocirculatory parameters such as blood pressure appear normal [113]. Comparing microvascular alterations between septic and non-septic critically ill patients helps elucidate underlying pathophysiological mechanisms and guides the development of targeted interventions [114].

Table 3 summarizes key diagnostic techniques used to assess microcirculatory dysfunction in sepsis, highlighting their advantages, limitations, and clinical relevance in managing critically ill patients.

Table 3: Diagnostic Analysis of Microcirculatory Dysfunction in Sepsis

Category	Aspect Analyzed	Description	Advantages	Disadvantages	Examples	References
Diagnostic Techniques Used	Sublingual Video Microscopy (SDF/OPS Imaging)	Direct visualization of microvascular flow abnormalities and capillary perfusion deficits.	Real-time, bedside assessment of microcirculation.	Operator-dependent, limited standardization.	Identification of capillary heterogeneity and sluggish flow in sepsis.	[115], [116]
	Near-Infrared Spectroscopy (NIRS)	Measures tissue oxygenation to assess microvascular dysfunction in real-time.	Non-invasive, continuous monitoring.	Limited spatial resolution, indirect measurement.	Detects impaired tissue oxygen extraction in septic shock.	[117], [118]
	Plasma Biomarkers (Lactate, Endothelial Activation Markers)	Biochemical markers reflecting endothelial dysfunction and microvascular impairment.	Easily accessible, quantitative assessment.	Nonspecific, affected by multiple factors.	Elevated lactate and angiopoietin-2 levels indicating sepsis severity.	[119], [120]
Key Microcirculatory Features	Capillary Perfusion Deficits	Impaired blood flow distribution at the microvascular level, leading to tissue hypoxia.	Helps explain oxygen delivery failure in sepsis.	Difficult to correct solely with macrocirculatory support.	Decreased proportion of perfused capillaries in septic patients.	[121], [122]
	Endothelial Dysfunction and Glycocalyx Damage	Disruption of endothelial barrier function, increasing vascular permeability, and inflammation.	Critical factor in sepsis progression and organ failure.	No direct bedside measurement is currently available.	Degradation of the endothelial glycocalyx leading to capillary leakage.	[123], [124]
	Oxygen Extraction and Mitochondrial Dysfunction	Sepsis-induced alterations in cellular oxygen utilization and mitochondrial energy production.	Key insight into metabolic failure in septic shock.	Challenging to measure in clinical settings.	Reduced oxygen consumption despite adequate oxygen delivery.	[125], [126]

According to Table 3, the assessment of microcirculatory dysfunction in sepsis highlights the necessity of a multimodal approach for accurate diagnosis and patient management. Sublingual video microscopy remains a valuable bedside tool for directly visualizing microvascular perfusion abnormalities [115,116], while near-infrared spectroscopy provides non-invasive, real-time insights into tissue oxygenation deficits [117,118]. Biomarkers such as lactate and endothelial activation markers offer an accessible means of assessing microvascular impairment [119,120], though they lack specificity and require correlation with other clinical parameters.

The distinct microcirculatory alterations observed in sepsis, including capillary perfusion deficits [121,122], endothelial dysfunction [123,124], and mitochondrial impairment [125,126], underscore significant pathophysiological differences compared to other critical illnesses. These findings suggest that conventional macrocirculatory-focused management strategies may be insufficient, emphasizing the need for personalized interventions targeting microvascular restoration.

Integrating microcirculatory assessment with inflammatory and metabolic biomarkers can enhance early risk stratification, optimize therapeutic strategies, and improve patient outcomes. This underscores the importance of a multidisciplinary approach, incorporating intensivists, infectious disease specialists, and hemodynamic monitoring experts to refine sepsis management and reduce mortality in high-risk populations.

Challenges

The treatment of sepsis in high-risk patient populations presents significant clinical and scientific challenges. Despite advancements in early diagnosis, antimicrobial therapies, and supportive care, difficulties persist in tailoring treatment strategies to meet the unique needs of vulnerable groups. Two major challenges are the identification of reliable prognostic markers to predict disease progression and the absence of standardized protocols for the personalized management of sepsis in special populations [127].

A primary obstacle in managing sepsis in these high-risk groups is the lack of robust prognostic markers that enable early risk stratification and guide treatment decisions. In the general sepsis population, biomarkers such as procalcitonin, C-reactive protein, and lactate levels are commonly used to assess disease severity and response to treatment [128]. However, in elderly patients, these markers may be less reliable due to an altered inflammatory response and atypical sepsis presentation. Similarly, in immunocompromised patients, the absence of a strong inflammatory response can lead to falsely low biomarker levels, delaying diagnosis and appropriate intervention [129]. Pediatric patients, especially neonates, have distinct immune responses that differ from adults, making it difficult to apply standard sepsis biomarkers to this population [130]. Recent studies have explored cytokines such as IL-6 and IL-10 as potential markers for sepsis severity in immunocompromised and pediatric patients, but further research is needed to validate their clinical utility. The absence of well-defined biomarkers complicates early detection, treatment optimization, and outcome prediction in these vulnerable groups [131].

Another key challenge is the lack of standardized protocols for the individualized management of sepsis in special populations. Although general sepsis guidelines exist, they do not always account for the unique physiological and immunological characteristics of elderly patients, pediatric patients, those with chronic diseases, or immunocompromised individuals [132]. For instance, fluid resuscitation strategies must be carefully adjusted in elderly patients with reduced cardiac and renal function to prevent fluid overload. Pediatric patients require weight-based adjustments for antibiotics and vasoactive medications, but there is no universal protocol guiding optimal dosing in neonates with sepsis [133]. Immunocompromised patients often require broader anti-microbial coverage, yet prolonged exposure to broad-spectrum antibiotics increases the risk of resistance and secondary infections, making antimicrobial stewardship particularly complex [134]. Similarly, in pregnant women, balancing maternal treatment with fetal safety is a significant challenge, as some life-saving antimicrobial and vasopressor therapies pose potential risks to fetal development. The absence of tailored sepsis management guidelines for these groups leads to variability in clinical practice and inconsistencies in patient outcomes [135].

Standardizing diagnostic and treatment protocols is essential for improving sepsis management in high-risk populations. Without clear evaluation and treatment criteria, clinical decision-making often relies on physician experience rather than evidence-based guidelines, leading to disparities in care across healthcare settings [136].

DISCUSSION

The findings from this analysis highlight the complexity of managing sepsis in high-risk patient populations and underscore the need for a personalized, multidisciplinary approach. The strength of evidence supporting various therapeutic interventions, prognostic indicators, and post-sepsis outcomes varies across patient groups, influencing decision-making for healthcare providers, researchers, and policy-makers.

Early and targeted antimicrobial therapy remains the cornerstone of sepsis treatment, with strong evidence (Level A) supporting its role in improving survival rates. The literature consistently emphasizes the importance of initiating broad-spectrum antibiotics within the first hour of suspected sepsis to reduce mortality, particularly in immunocompromised patients and neonates who are highly susceptible to rapid disease progression [137]. However, antibiotic stewardship remains a critical concern, as prolonged or inappropriate antimicrobial use contributes to resistance, especially in patients with recurrent sepsis [138].

Supportive interventions such as hemodynamic monitoring and organ support therapies play a crucial role in managing sepsis in elderly patients, pediatric populations, and those with chronic comorbidities [139]. Evidence suggests that goal-directed fluid re-suscitation and vasopressor therapy improve outcomes in patients with sepsis-induced hypotension (Level A). However, the literature also indicates that fluid overload can worsen prognosis, particularly in elderly patients with cardiac or renal impairment, necessitating individualized resuscitation strategies [140]. Pediatric patients require weight-based hemodynamic adjustments, yet a lack of standardized protocols for fluid management in neonatal sepsis creates challenges in optimizing treatment [141].

The role of immunotherapy in sepsis treatment remains an evolving area of research, with emerging evidence suggesting potential benefits for immunocompromised patients. Studies exploring the use of intravenous immunoglobulins (IVIG) and cytokine-targeting therapies indicate possible improvements in immune function and infection control (Level B) [142]. However, data remain inconclusive, and the heterogeneity of immune responses in different patient groups complicates the identification of optimal candidates for such therapies [143].

Post-sepsis outcomes and long-term patient recovery have become increasingly recognized as critical aspects of sepsis care, particularly with the identification of post-sepsis syndrome (PSS) [144]. Studies show that sepsis survivors, particularly elderly patients and those with pre-existing comorbidities, frequently experience persistent physical, cognitive, and psychological impairments that reduce their quality of life (Level A) [145]. The literature highlights the need for early rehabilitation programs, including physical therapy and mental health support, to improve post-sepsis functional outcomes [146]. Pediatric patients, though generally more resilient, may experience long-term developmental delays, while immunocompromised individuals remain at high risk for recurrent infections [147].

The analysis of sepsis treatment and outcomes in high-risk populations underscores the need for a more personalized approach to management. While early antimicrobial therapy, hemodynamic support, and organ protection strategies are well established, optimizing treatment for specific patient groups remains a challenge [148,149]. Further research into immunomodulatory therapies, targeted resuscitation strategies, and post-sepsis rehabilitation programs could improve outcomes for vulnerable populations. For healthcare systems and policy-makers, prioritizing research funding and developing population-specific guidelines will be crucial in advancing sepsis care.

CONCLUSION

The findings of this analysis reinforce and expand upon the existing research on sepsis management in high-risk patient populations, emphasizing the distinct pathophysiological mechanisms and therapeutic challenges that differentiate these groups from the general sepsis population. The evidence strongly supports the fundamental role of age-related immune changes, comorbid conditions, and immune suppression in altering sepsis progression, response to treatment, and long-term recovery. These differences explain the variability in treatment outcomes and underscore the necessity for patient-specific, tailored therapeutic approaches.

From an antimicrobial therapy perspective, the literature confirms that early and targeted antibiotic administration remains the cornerstone of sepsis treatment, particularly in immunocompromised patients and neonates, where delayed intervention significantly worsens prognosis. However, the growing concern of antimicrobial resistance in patients with recurrent sepsis highlights the urgent need for enhanced antimicrobial stewardship programs and the integration of rapid molecular diagnostics to optimize therapy selection. The challenge of balancing broad-spectrum coverage with the risk of resistance remains a key consideration in long-term sepsis management.

The role of hemodynamic support and organ protection strategies in sepsis treatment is well established, with evidence favoring individualized fluid resuscitation and vaso-pressor therapy based on patient-specific factors such as age, renal function, and baseline cardiovascular status. While goal-directed resuscitation strategies improve survival, the risk of fluid overload in elderly and chronically ill patients necessitates a more precise, dynamic approach to fluid management. The increasing use of bedside ultrasonography and advanced monitoring techniques presents an opportunity to refine resuscitation protocols and improve patient outcomes.

The growing recognition of post-sepsis syndrome (PSS) highlights the need for a more comprehensive approach to sepsis care, extending beyond the acute phase to address long-term health complications. Studies confirm that sepsis survivors, particularly elderly individuals and those with preexisting conditions, frequently experience persistent physical, cognitive, and psychological impairments that significantly impact their quality of life. Post-sepsis rehabilitation programs, including structured physical therapy, cognitive assessments, and mental health support, are increasingly recognized as essential components of recovery. However, gaps remain in the availability and accessibility of these services, underscoring the need for healthcare systems to prioritize long-term sepsis care.

These findings highlight the importance of integrating personalized therapeutic strategies, advanced diagnostic technologies, and long-term rehabilitation programs into sepsis management.

Implications for Future Research

Given the limitations of standard sepsis management in high-risk populations, future research should focus on developing personalized treatment strategies that account for immune dysfunction, comorbid conditions, and age-related physiological changes. Studies investigating immunomodulatory therapies, such as IL-6 and IL-10 inhibitors, could provide new therapeutic avenues for immunocompromised patients who fail to mount an adequate immune response. Additionally, research into host-directed therapies, including immune checkpoint inhibitors and cell-based treatments, may help restore immune balance in patients with immune exhaustion or dysregulated inflammatory responses.

The growing threat of antimicrobial resistance, particularly in patients with recurrent sepsis, underscores the need for novel antibiotic stewardship strategies. Future studies should explore rapid molecular diagnostics and point-of-care pathogen identification tools to facilitate early, targeted antibiotic therapy while minimizing unnecessary broad-spectrum antibiotic use. Additionally, research into alternative antimicrobial approaches, such as bacteriophage therapy and antimicrobial peptides, could provide effective solutions for multidrug-resistant infections. The development of nanotechnology-based drug delivery systems to enhance antibiotic penetration into infected tissues and biofilms should also be a priority.

Hemodynamic monitoring and resuscitation strategies in sepsis require further refinement to improve outcomes in specific patient populations. Research into precision-guided fluid resuscitation, incorporating real-time hemodynamic assessment tools such as microcirculatory imaging and noninvasive cardiac output monitoring, could help tailor fluid therapy and prevent complications such as fluid overload in elderly and chronically ill patients. Additionally, studies comparing restrictive versus liberal fluid strategies in different patient populations could provide insights into optimizing volume resuscitation while minimizing adverse effects.

The long-term impact of sepsis, particularly post-sepsis syndrome (PSS), remains an area requiring further exploration. Future research should focus on identifying bi-omarkers that predict long-term cognitive, physical, and psychological impairments following sepsis. Large-scale longitudinal studies evaluating the effectiveness of rehabilitation programs, including physical therapy, neurocognitive interventions, and mental health support, are needed to establish standardized post-sepsis care protocols. Investigating the role of gut microbiome alterations in post-sepsis recovery may also provide opportunities for microbiome-targeted therapies to improve immune homeostasis and overall health outcomes.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration for publication elsewhere. This research received no external funding.

Authors' contribution

Conceptualization, G.P.G. and D.R.T.; methodology, G.P.G and D.R.T; software, M.B.N and I.S.C.; validation, G.P.G and L.P; formal analysis, R.M.S and C.P.; investigation V.T.G and I.S.C.; resources G.P.G, L.P and V.T.G..; data curation, R.M.S., L.P. and M.B.N.; writing—original draft preparation G.P.G. and C.P.; writing—review and editing, G.P.G,. Abstract: Preventive medicine plays a crucial role in ensuring the efficiency of healthcare systems, and laboratory investigations represent one of its main pillars. However, achieving an optimal balance between the benefits and costs of testing remains a challenge. Caught between public expectations, appropriate test utilization, and the need for adequate physician training in test ordering, enhancing patients' understanding and knowledge becomes essential. To explore this aspect, a general online survey was conducted, completed by 321 respondents. The results show that, while respondents generally followed physicians' recommendations, many also sought laboratory testing on their own initiative. Direct access to laboratory services - facilitated by the widespread availability of private laboratories - has become a common practice. This raises concerns about the potential overuse of laboratory testing and underscores the importance of further investigating the factors driving patient self-empowerment. Enhancing shared decision-making between patients and physicians is essential to optimize the benefits of testing, minimize unnecessary costs, and reducing the risk of health-related anxiety.

Keywords: laboratory investigations; routine testing; public health; medical education; healthcare overuse

INTRODUCTION

Laboratory testing plays a critical role in the diagnosis, monitoring, prognosis, and treatment of diseases. In modern healthcare, best practice emphasizes the principle of shared decision-making. Although this approach is more commonly applied to therapeutic decisions, it is equally relevant to laboratory investigations and diagnostic testing, as highlighted by Watson et al. While patients rarely request blood tests directly, they often perceive laboratory investigations as a meaningful step in the management of their health condition and as an indication that their physician is taking their concerns seriously. For patients, laboratory results are expected to provide clear answers or solutions, whereas physicians typically use them as tools to rule out serious conditions and to guide clinical reasoning. Due to the discrepancy between patients' expectations and the lack of adequate explanations regarding the actual purpose of the investigations, some patients are disappointed when the tests do not provide a clear diagnosis or concrete solutions for their medical condition [1].

In the context of individuals' tendency to absolutize the role of laboratory testing - as either a means of validating their health status or resolving medical issues - direct-to-consumer laboratory testing emerges as a form of self-empowerment. This is a challenge for the safety and efficacy of healthcare because it allows patients to obtain test results without physician referral, clinical interpretation, or a clear understanding of the limitations related to the test's analytical and diagnostic performance or its overall quality [2].

In the context of an increased volume of test requests, there is a potential for negative consequences. When performed by physicians, ordering unnecessary tests may lead to overdiagnosis, which can result in unwarranted treatments, potential adverse effects, and increased costs for the healthcare system. Contributing factors

include patient expectations and pressure, as well as physicians' fear of legal liability, all of which may influence the decision to order tests that are not clinically justified [3].

Furthermore, the education and training of physicians in ordering adequate laboratory investigations might be a challenge. According to a study conducted by Fung et al., the majority of residents in family medicine ordered appropriate tests from a list of 38 laboratory investigations for prevention and screening purposes; however, the majority of the participants ordered at least one inappropriate test per patient (average from 3.3 to 5.7 per patient), leading to excessive costs. Several factors have contributed to the tendency to order unnecessary laboratory tests, including patient requests, fear of overlooking important clinical details, working in solo practice, and concerns about potential litigation [4].

While the main reason why healthy individuals visit the primary care facilities is preventive check-ups, and in this context, the family physicians order a high number of screening tests, the overuse of laboratory investigations has decreased from 1978 [5].

Considering the major influence in balancing overuse and effective screening of individual perceptions, understanding, and emotional responses regarding the role of laboratory testing, this study aims to provide general insights from individuals living in Romania. It explores their opinions, habits, behaviors, and knowledge related to laboratory testing, intending to inform the design of future representative studies.

MATERIALS AND METHODS

A survey was conducted using an online data collection tool (Google Forms), which included questions with predefined answers. Respondents selected the answers they deemed most appropriate. The questions addressed various topics related to medical laboratory investigations, including knowledge, opinions, habits, and behaviors. Participation in the survey was voluntary; the link to the form was accessible to anyone, and respondents' completion of the survey was automatically considered as consent to participate in the study. An introductory section provided information about the study's purpose.

Data were collected using a general data collection instrument rather than a validated questionnaire, aiming to capture a broad perspective and highlight insights and new areas for research, rather than yielding quantitative and generalizable results.

The data were centralized and analyzed using Microsoft Excel and Google Sheets. Relative frequencies were calculated and presented in tables and charts. This study employed descriptive statistics only, reflecting its exploratory nature and the self-selected sample. Therefore, no inferential analyses were performed, and causal or generalizable conclusions cannot be drawn. Further research with representative samples and appropriate analytical methods is needed to investigate potential associations.

RESULTS

1. Characteristics of the study respondents and health status

A total of 321 respondents participated in the survey, with an average age of 29 years (ranging from a minimum of 18 to a maximum of 81 years). Among the participants, 85% identified as female and 15% as male. Geographically, 22% of respondents resided in rural areas, and 78% in urban settings. The educational and professional backgrounds of the respondents are detailed in Table 1. Notably, 27% reported having no relatives or close friends working in the healthcare field. Regarding self-reported health status, 77% of respondents considered themselves healthy, while 23% indicated they suffered from chronic conditions, as illustrated in Figure 1.

Table 1: Educational and professional profile of the respondents

Level of studies	Middle school	High school	Higher education
	1.5 %	27%	72%
Occupation	Student	Employee	Other
	45%	50%	5%
Study or work in one of the following fields: health, medicine, veterinary medicine, dentistry, pharmacy, biology		No	Yes
		55%	45%

The majority of respondents rated their overall health status as good or very good; however, most also reported being concerned or very concerned about their health, as shown in Figure 2.

Several behaviors were reported by respondents as being associated with their health-related concerns, as presented in Table 2.

Figure 1: The relative frequency of chronic diseases among respondents who reported having illnesses

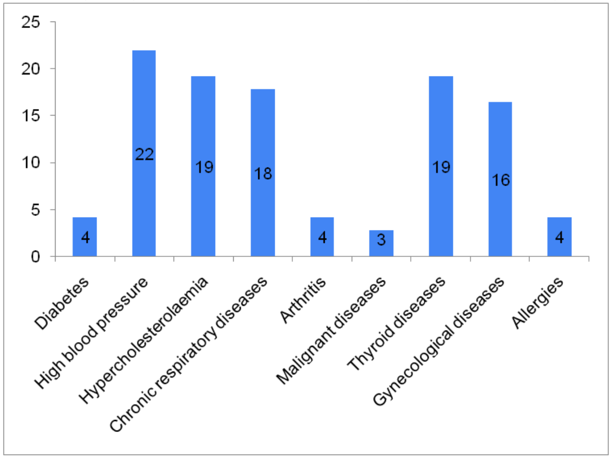

Figure 2. Self-perception of the overall health status (a) and level of concern related to the health status (b)

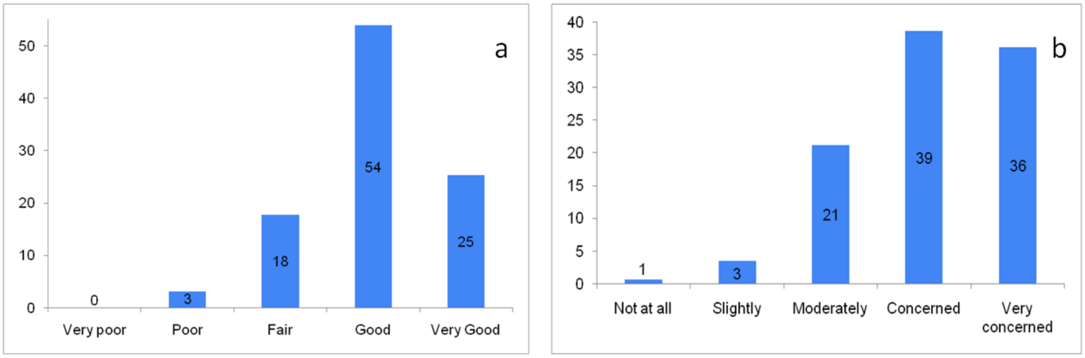

Table 2. Self-reported behaviors associated with health concerns – statements and percentages of respondents in agreement

Behavior linked to health concerns	Relative frequency
I don't consider myself concerned about my health.	4%
I frequently see a doctor for preventive purposes.	28%
I visit the doctor immediately when symptoms appear.	47%
I get medical tests done frequently.	50%
I get laboratory tests done as soon as I notice symptoms.	25%
I go directly to the pharmacy to request treatment if I notice something is wrong.	21%
Concern about my health makes me think about it all the time or frequently.	15%
Concern about my health makes me anxious.	20%
I adopt a healthy lifestyle to be in the best possible health.	36%
I'm afraid of catching infectious diseases in various everyday situations.	26%
I generally postpone going to the doctor for as long as possible.	11%
When I should go to the doctor, I prioritize it over other professional or personal matters.	38%
When I should go to the doctor, I first deal with other professional and personal matters and only then make an appointment.	13%

Opinions about laboratory investigations

Table 3 summarizes respondents' views and knowledge about medical laboratory investigations, their importance, and the recommendations they reported being familiar with regarding laboratory testing.

Table 3: Opinions about laboratory investigations – statements and percentages of respondents in agreement

How important do you consider routine laboratory tests to maintaining health?	
Very important, laboratory tests are essential for detecting and monitoring health problems.	87%
Moderately important, laboratory tests may be useful in certain situations, but are not always necessary.	12%
I do not consider laboratory tests essential for maintaining health.	1%
Do you think it is important to have regular laboratory tests, even if you are healthy?	
Yes, to detect potential health problems in their early stages.	90%
No, if I don't have symptoms, I don't need tests.	2%
It depends on each person's age and lifestyle.	7%
I am not sure.	1%
How well do you think laboratory test results indicate health status?	
The tests show exactly what health problems I have.	25%
Most of the time, the analyses are indicative.	41%
The tests cannot accurately indicate what health problems I have, regardless of their nature.	4%
Certain tests can indicate the exact disease, while others assess the general state of health.	29%
What do you consider to be the ideal approach?	
We should have all kinds of tests done frequently to make sure we are healthy.	51%
We should perform several more important types of tests frequently to ensure we are healthy.	48%
I do not believe that it is necessary to perform routine tests frequently to detect possible health problems.	1%
Do you think that your doctor recommends enough tests for you?	
I didn't need to see my family doctor/specialist.	8%
Yes, I believe I am receiving the necessary recommendations for my health.	63%
I am not sure.	8%
No, I think I am being recommended too many tests.	2%
No, I think that too few tests are recommended for me.	16%
I don't do laboratory tests.	2%
How frequently do you think laboratory tests are recommended for someone your age?	
3-4 times a year	6%
1-2 times a year	83%
Once every 2-3 years	2%
Less often	1%
No specific time frame is recommended	3%
What is your level of confidence in the results of laboratory tests?	
Very high	28%
High	61%
Moderate	11%
Low	0%
Absent	0%
How do you see the doctor's role in interpreting laboratory test results?	
As an essential guide in understanding the results.	90%
Like someone who should only be consulted in case of problems.	6%
I do not consider it necessary to have a doctor interpret it, as there is enough information available on the internet.	1%
No opinion.	2%

Do you think laboratory tests should be used more in prevention?	
Yes, it could help prevent some conditions.	62%
Yes, it could help detect diseases in their early stages.	31%
No, it could cause unnecessary worries.	1%
It depends on each individual case.	5%
How do you evaluate the experience during sample collection for laboratory analysis?	
Comfortable and without problems.	55%
Acceptable, there is potential for improvement.	40%
Uncomfortable and unpleasant.	4%
I have no personal experience in this regard.	1%
Which of the following aspects do you think could improve your experience while performing laboratory tests?	
Reducing waiting time for results.	12%
Lower costs or covered by health insurance.	60%
Better communication and explanation of results.	13%
Reducing waiting time for sample collection.	2%
Do you consider that laboratory results are managed with confidentiality in mind?	
Yes, I trust that they are treated confidentially	77%
I am not sure	15%
No, I have doubts about their confidentiality	2%
I have no personal experience with this	3%
No opinion	2%
Do you think there is enough public education about the importance and usefulness of laboratory tests?	
Yes, there is enough public education.	7%
No, more education would be beneficial.	87%
Not sure.	4%
I don't think public education would make a difference.	2%
No opinion.	1%
When you receive the results of laboratory tests, do you consider it useful to automatically receive explanations of the results in a formal setting?	
No, because I understand all the content and I don't need any other information.	7%
No, because I can find the necessary information by asking people I know or searching the internet.	1%
I do not know.	1%
Yes, I think it would be useful to receive explanations of the results every time I have my lab tests.	88%

Behavior of respondents

Regarding how the respondents deal with the results of medical laboratory investigations, most respondents reported either seeking medical advice or requesting feedback about their health, as shown in Figure 3.

Table 4 presents self-reported adherence to physicians' recommendations regarding laboratory tests, as well as respondents' motivation, testing frequency, and behaviors related to receiving laboratory results.

The majority of the responders reported that the fear of blood or the fear of blood collection does not prevent them from having their laboratory tests done, as presented in Figure 4.

With regard to the entity involved in laboratory investigations, the majority of the responders preferred private laboratories to have their tests done, as shown in Figure 5.

Access, availability, barriers and knowledge related to laboratory testing

In the group of responders who were employed, 48% mentioned that their employer does not provide access to routine laboratory testing, 47% that they have access to routine laboratory testing once a year or more often, and 4% that they have access to routine laboratory testing from their employer every few years.

The responders considered costs and lack of time as the main factors that prevent them from having their routine laboratory testing done, as presented in Figure 6.

Figure 3: Respondents' attitudes toward normal (a) and abnormal (b) laboratory results

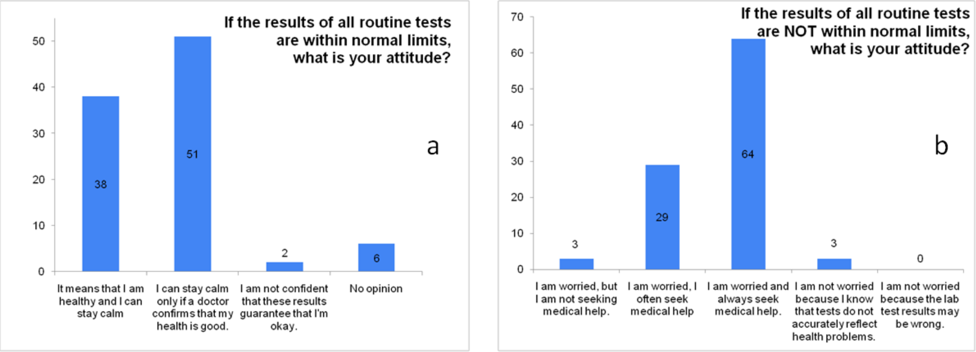

Table 4: Behaviors related to undergoing laboratory investigations, compliance with physicians` indications and dealing with lab test results – statements and percentages of respondents in agreement

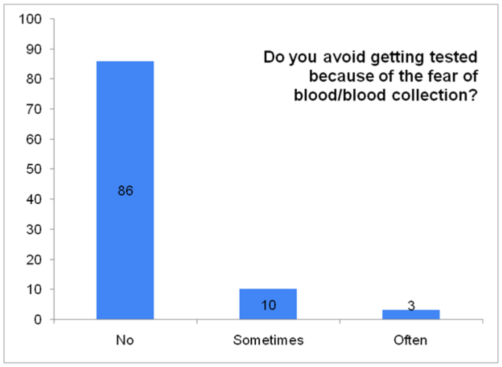
Do you do laboratory tests on your own initiative or on the recommendation of a doctor?	
On the recommendation of a family doctor/specialist.	23%
On my own initiative.	24%
Both on the recommendation of a doctor and on my own initiative.	51%
I don't do laboratory tests.	2%
How often do you do your routine lab tests?	
Twice a year or more often	23%
Once a year	61%
Once every few years	6%
Only when I have a health problem	8%
Never	2%
When you do laboratory tests on your own initiative, what is the motivation? (multiple choice)	
I do not do my laboratory analyses on my own initiative.	14%
I want to make sure that my health remains good.	63%
I want to know if I have a health problem, even if I don't have symptoms.	52%
I have chronic illnesses or other conditions and for this reason, I want to have tests done.	13%
When you performed laboratory tests on the doctor's recommendation, for what purpose were you guided in this direction? (multiple choice)	
To establish a diagnosis.	46%
To follow up a disease.	24%
To perform routine tests without having a health problem.	69%
I did not do any tests recommended by a doctor.	6%
Do you always do your lab tests when your doctor recommends them?	
Always	74%
Often	21%

Rarely	3%
Never	2%
When you don't do lab tests following your doctor's recommendation, what is the motivation? (multiple choice)	
No medical tests were recommended to me.	26%
I was healthy and it was just routine tests.	30%
I did not have enough time.	19%
I did not have access to a collection point/medical analysis laboratory.	7%
I didn't see the usefulness of the analyses in that context.	6%
The costs were too high.	17%
What would you do if your tests are outside normal limits, and the doctor tells you that everything is fine with your health status?	
I turn to another doctor.	35%
I inquire into other sources and make my own decisions for diagnosis and treatment.	7%
I continue the investigations and repeat the tests.	40%
I trust the doctor and do nothing extra.	17%
What is your main source of information regarding laboratory tests? (multiple choice)	
My physician	89%
Acquaintances who work in the medical field	33%
Healthcare related websites	13%
Family, friends and acquaintances who do not work in the medical field	11%
I did not request/seek information about the analyses	3%
Books, magazines and specialized articles	17%
Websites of laboratories and clinics	28%
Social media groups	1%

Figure 4: The impact of the fear of blood or blood collection on having laboratory testing done



The knowledge and opinions about the laboratory investigations reimbursed by the public healthcare insurance system are presented in Table 5.

The majority of the responders have a sample collection facility or a medical laboratory within a reasonable walking distance from their home and reported that the distance from it does not influence their decision to have their routine tests done (Figure 7).

DISCUSSION

Overall, respondents were optimistic about their health status, with most rating it as good or very good. Nevertheless, the majority also reported being concerned or very concerned about their health. This particular perception may influence their attitudes and behaviors related to laboratory investigations. For example, health anxiety has a major impact on healthcare use [6].

Despite expressing concern about their health, fewer than one-third of respondents reported seeking preventive medical care. Approximately 40% reported adopting a healthy lifestyle, and less than half indicated that they consult a physician promptly upon noticing symptoms. More than 60% agreed that laboratory testing could be used more extensively for prevention, and over 30% believed that laboratory tests could be better utilized for early disease detection. However, half of the respondents considered that they already undergo laboratory tests frequently, while only a quarter reported getting tested when symptoms occur.

In general, respondents demonstrated awareness of the importance of laboratory testing for disease diagnosis (including early detection) and monitoring. They also acknowledged that the variety of available laboratory tests serves different purposes in healthcare. While less than one-third expressed very high confidence in laboratory test results, more than 60% reported having confidence in them overall. Additionally, nearly 80% of respondents stated that they trust laboratory investigations are handled confidentially.

Figure 5: Preferences for public and private laboratories

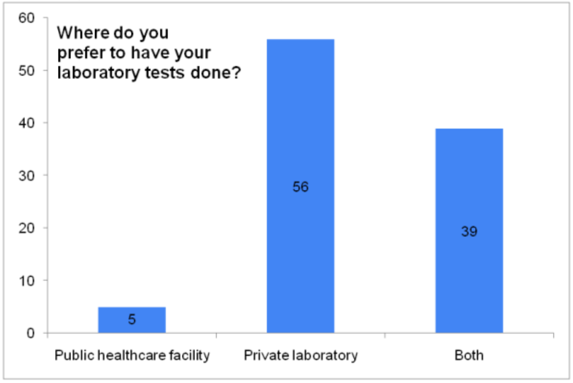


Figure 6. Main barriers to routine laboratory testing

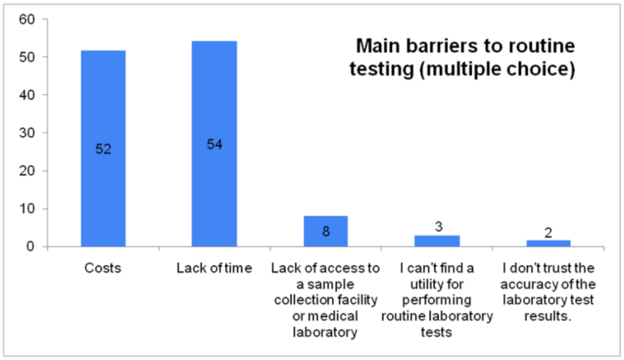

Table 5: Opinions and knowledge of the responders about the reimbursement of the costs for laboratory investigations – statements and percentages of respondents in agreement

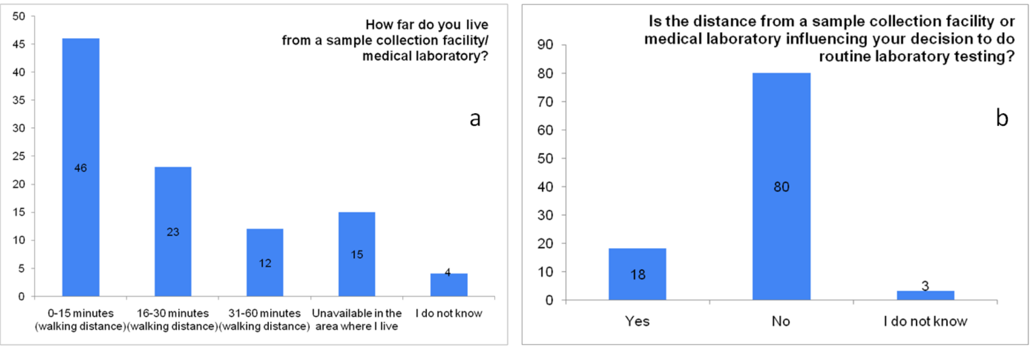
Are laboratory tests reimbursed by the public healthcare insurance system?	
I don't know this information.	30%
Routine tests are reimbursed once a year.	26%
Laboratory tests are reimbursed, regardless of whether they are routine or not, once a year.	4%
Routine tests are reimbursed whenever a referral from the family doctor is used.	33%
Lab tests are reimbursed, regardless of whether they are routine or not, whenever needed.	3%
Lab tests are reimbursed only for those with an established diagnosis.	2%
Lab tests are reimbursed only for hospitalized persons.	1%
Have you ever benefited from laboratory tests reimbursed by the public healthcare insurance system?	
Rarely	15%
Every time/almost every time	21%
Often	36%
I do not know	10%
No	17%

Patients often perceive laboratory tests as inherently accurate and confidential, yet studies suggest gaps in their understanding of these concepts. Sankar et al. highlighted that misconceptions about confidentiality can undermine trust, with some patients overestimating privacy safeguards [7]. Educating patients about the accuracy limits of tests and existing privacy protections may strengthen their engagement and promote informed participation in healthcare decisions [8].

With regard to healthcare received from physicians and the medical system, most respondents considered that, in general, they are adequately recommended for laboratory testing. Overall, routine laboratory testing appears to be driven equally by the respondents' own initiative and by physicians' recommendations. Patients who undergo laboratory testing on their own initiative are motivated by various factors, including the desire to confirm their perceived good health status or personal experiences—such as witnessing family members or acquaintances being diagnosed or saved through timely laboratory testing [3]. The growing availability of direct-to-consumer testing has enabled patients to access laboratory analysis without a physician's mediation, but some studies highlight potential risks, including misinterpretation of results and unnecessary anxiety [9]. According to the results of Shaked et. al, in the case of patient-requested laboratory investigation, even after the doctor explained why the tests were unnecessary, the majority of patients expected to receive a referral for laboratory testing, likely due to the perception that blood tests are objective and reliable tools for validating one's health status [3].

Figure 7: The availability of sample collection facilities or medical laboratory close to the residence of respondents (a) and its impact on decisions regarding laboratory testing (b)



The main reasons for undergoing laboratory tests without a medical recommendation are to ensure good health and to detect early or subclinical diseases. Balancing preventive strategies with patient education about the limitations and risks of indiscriminate testing is essential to avoid fostering a culture of overmedicalization [10]. Approximately 90% of the respondents of this study acknowledged the importance of physicians in explaining laboratory test results. Similarly, nearly 90% believed it would be beneficial to receive explanations of their results in a formal setting each time they undergo laboratory investigations.

Around half of the participants reported that, when laboratory results fall within the biological reference interval, they feel reassured only after receiving confirmation from a physician that their health status is adequate. When routine test results fall outside the reference interval, more than 60% of respondents stated that they always seek medical help, while nearly 30% reported doing so often. According to a study performed by Marloes et al., patients overestimate the performance of blood testing, and results within normal limits were automatically seen as proof of an optimal health status. However, this study included only patients who voluntarily presented to the general practitioner for blood tests [11].

Furthermore, the vast majority of respondents (approximately 90%) identified physicians as their primary source of information regarding laboratory tests. Random online, non-professional sources were not commonly used. Instead, acquaintances working in healthcare and official websites of medical institutions were reported as the second and third most frequently cited sources of information, respectively. On the other hand, a survey by Cocco et al. revealed that an important part of respondents searched for explanations of lab results online before consulting a clinician, sometimes resulting in inappropriate self-diagnosis [12]. McMullan et al. found that patients using online resources for interpreting laboratory results often encounter conflicting or inaccurate information, leading to confusion and heightened anxiety [13].

When routine testing is recommended by a physician, the majority of respondents comply with the recommendation and undergo testing. Among those who do not comply, the main reasons reported are the perception of being in good health due to the routine nature of the check-up, lack of time, and associated costs. Adherence to recommended laboratory testing is essential for effective clinical management, but can be suboptimal. In patients with diabetes, a large registry study found that approximately 1 in 7 did not complete essential lab tests (such as HbA_1c or creatinine) within six months of ordering. Key predictors of better adherence included older age, female sex, and orders placed during face-to-face visits [14].

The majority of respondents considered that routine laboratory testing should be performed once or twice per year. Over 60% reported undergoing routine testing once annually, while more than 20% reported doing so twice a year or more frequently. The optimal frequency for routine blood testing depends on individual health status and clinical context. For healthy adults, many guidelines recommend annual basic panels during preventive visits, but more frequent testing is justified in chronic conditions or medication monitoring [15].

Although fear of blood or blood withdrawal is generally common [16], only 4% of respondents in this study described the sample collection procedure as uncomfortable or unpleasant. Additionally, nearly 90% reported that such fears do not influence their decision to undergo laboratory testing.

From the respondents' perspective, reducing waiting times for sample collection or results, as well as receiving more information and explanations about laboratory investigations and their outcomes, were not considered priorities for improvement. The primary issue identified was the cost of laboratory investigations and their coverage by health insurance.

Cost represents a significant concern, especially given that the majority of respondents reported preferring to have their laboratory tests performed in private laboratories rather than in public healthcare facilities. Additionally, lack of time and financial constraints were reported as the main barriers to undergoing laboratory testing.

Due to the widespread availability of private laboratories in Romania and access to their services without the need for a physician's referral, two specific aspects emerge: firstly, the healthcare system lacks control over potential overuse of testing, and secondly, the costs are often entirely supported by the patient. This situation may differ in other countries, where the overuse of laboratory investigations is potentially driven by the extensive coverage provided by public or private health insurance. When testing is widely accessible and patients and the healthcare provider are not directly burdened by the costs, the likelihood of overuse may increase [17].

Respondents appeared to have limited knowledge regarding the coverage and conditions for laboratory investigations under the public health insurance system, and few reported utilizing reimbursed laboratory tests.

Overall, respondents expressed the view that there should be increased public education regarding the importance and benefits of laboratory testing. Patients often struggle to understand the need for certain laboratory tests and their results, highlighting the importance of public education in laboratory medicine [18].

Overall, the responses to questions regarding laboratory medicine suggest that the general public in Romania may have high expectations for routine testing. Currently, there are no regulations in Romania that restrict access to direct-to-consumer testing. While direct-to-consumer access to routine laboratory investigations is generally permitted across countries, some nations have imposed restrictions on direct access to genetic testing [19]. Although most genetic conditions are rare, for example, familial hypercholesterolemia is a relatively common genetic disorder [20]. In the absence of regulatory limitations, such conditions may be perceived by the general public as suitable for direct-to-consumer testing - particularly given the high prevalence and awareness of hypercholesterolemia. However, this raises the risk of misinterpretation, since direct-to-consumer tests for this condition often lack optimal performance for accurate detection [21].

The current study has several limitations. First, the data collection instrument was not a validated questionnaire, which limits the generalizability of the findings. Additionally, respondents were self-selected, resulting in a sample that is not representative of the general population. Moreover, the sample did not uniformly or comprehensively cover all demographic backgrounds of Romanian citizens, with most respondents holding higher education degrees and residing in urban areas. Finally, all data were self-reported, relying on respondents' subjective perceptions and, in some cases, their memory and ability to estimate the frequency of events (e.g., how often they underwent routine laboratory testing).

However, it is essential to conduct this type of exploratory research, which is less quantitative in nature, to identify key areas for further investigation. This study provided a rapid assessment of various aspects related to patients and laboratory testing, offering a foundation for more detailed future research.

Future studies should build on the exploratory findings of this research by employing validated questionnaires and representative samples to enhance the generalizability of results. Further investigation is needed to understand the multifaceted factors influencing patients' adherence to physician recommendations for laboratory testing, including psychosocial, economic, and cultural determinants. Additionally, evaluating the impact of public education campaigns on patients' knowledge, trust, and behavior regarding laboratory investigations could provide valuable insights. Qualitative research methods, such as in-depth interviews and focus groups with both patients and healthcare providers, would offer a deeper understanding of the perceptions, fears, and informational needs surrounding laboratory testing. It is also important to explore disparities in access to laboratory services across urban and rural settings and among different socio-economic groups. Finally, examining the role of cost and health insurance coverage in shaping patients' decisions to undergo laboratory testing would contribute to the development of targeted interventions to reduce barriers and improve utilization.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No artificial intelligence automatically generated text was inserted in this manuscript, and no image was previously published in another journal or is under consideration for publication elsewhere. This research received no external funding.

Acknowledgments

The research group was formed with the support of the Medical Research Education Project (https://ssmb.ro/departamente/#scome) of the Medical Students' Society of Bucharest (SSMB).

Ethics approval and consent to participate

This study was conducted using an online questionnaire that was publicly available and open to the general population. Participation was voluntary, self-selected, and anonymous. No personal or identifiable data were collected, and no recruitment of patients was involved. Information about the purpose and nature of the study was provided at the beginning of the form. Completion and submission of the form were considered as an indication of informed consent to participate in the study. Considering all these aspects, the study was conducted in compliance with ethical guidelines.

Abstract: The Human Immunodeficiency Virus (HIV) and the Acquired Immunodeficiency Syndrome (AIDS) remain significant public health concerns worldwide. This review seeks to present an updated perspective on the spread, consequences, and control measures of HIV/AIDS, focusing on military personnel as a particular at-risk group. It starts by outlining general information about the transmission of the virus and summarizing recent global epidemiological trends. This review further explores the difficulties that HIV/AIDS presents in military settings, including policies regarding the management of service members living with the virus. Additionally, it examines several prevention strategies implemented by militaries around the world, such as educational programs, provision of condoms, and efforts to reduce the stigma associated with the infection.

Keywords: HIV; AIDS; military population; prevention; treatment; management

INTRODUCTION

The Human Immunodeficiency Virus (HIV) was first presented in 1983 as a non-transforming retrovirus [1]. This virus targets CD4+ T lymphocytes and is responsible for Acquired Immunodeficiency Syndrome (AIDS) in individuals with the infection [2]. This condition is characterized by two human lentiviruses: HIV-1 and HIV-2, with transmission occurring exclusively from human to human. Typically, in the absence of a treatment, HIV-1 infection can lead to AIDS, a syndrome associated with significant mortality rates [3]. Both HIV-1 and HIV-2 are RNA viruses that carry the necessary information for the synthesis of the viral proteins essential for the replication and assembly of the virus [4].

HIV transmission occurs either horizontally or vertically [5]. Vertical transmission is the most common way for children to acquire the infection, either in utero, during childbirth, or through breastfeeding [5,6]. Horizontal transmission involves needle sharing or unprotected sexual contact [5,7,8].

One population that has been identified as vulnerable to acquiring HIV infection is military personnel, due to frequently reported high-risk sexual behaviour [9,10] or to their high mobility and exposure to biologically foreign environments [11,12].

Aim

This literature review explores the challenges faced by military populations in the context of HIV/AIDS and presents prevention strategies and proposed solutions for effective prevention and control in this high-risk group.

MATERIALS AND METHODS

This paper examines the medical literature concerning HIV/AIDS, as well as the public information disseminated by state agencies regarding programs and strategies aimed at preventing HIV transmission among military personnel.

RESULTS

HIV/AIDS: General Overview and Key Statistics

At the end of 2022, the World Health Organization reported that 39 million people were living with HIV, including 1.5 million children. That year, 1.3 million people contracted the virus, reflecting a 38% decline compared to 2010, when 2.1 million new cases were reported [13].

Concerning HIV-related mortality, 2022 saw 630,000 deaths attributed to the virus, down from an estimated 1.3 million deaths in 2010. This represents a 51% decrease over a 13-year period.

In terms of treatment, around 29.8 million people received antiretroviral therapy (ART) in 2022. Among those infected that year, 86% were aware of their HIV status, 76% had begun treatment, and 71% had successfully achieved viral suppression [13].

The African continent remains the most affected globally by HIV, with an estimated 25.6 million individuals living with the virus. Within this group, 90% are aware of their status, 82% receive antiretroviral therapy (ART), and 76% have achieved suppressed viral loads. The region has also seen a significant drop in incidence per 1,000 uninfected individuals. Along with a 56% decrease in AIDS-related deaths since 2010, down to an estimated 380,000 annually [13].

The European Region has an estimated 3 million people living with HIV. Of these, 72% know of their status, 63% are undergoing treatment, and 60% have achieved suppressed viral loads. Roughly 1.9 million individuals are on ART. However, Europe has experienced a rise in HIV incidence over the past decade, from 0.16 to 0.20 per 1,000 uninfected people, alongside approximately 180,000 new infections reported in 2022. AIDS-related mortality has also increased by 37% since 2010, with an estimated 52,000 deaths recorded in 2022 [13].

In Romania, according to the latest data, 716 people were diagnosed with HIV/AIDS in 2023. Over the period from 1985 to 2023, a total of 18,389 individuals have been recorded as having the disease, with 8,556 losing their lives due to HIV-related causes [14].

Epidemiology of HIV in Military Populations

Military populations represent a unique demographic in the global HIV epidemic [11,12], being predominantly composed of young adults [15,16] and often deployed to environments where risk behaviors may increase - factors shown to contribute to new infections among U.S. Army Soldiers [17].

HIV incidence differs substantially across regions, with particularly high rates observed in certain areas of sub-Saharan Africa and Southeast Asia. In the United States, while overall HIV prevalence is lower, military personnel are not exempt. Despite strict screening protocols, they are not exempt [18]. As of March 2021, over 170,000 U.S. service members were deployed globally, marking the largest international military presence at that time[19]. By June 2024, approximately 166,000 active-duty U.S. troops- representing 12.8% of the total force- were still stationed overseas [20].

In 2021, the HIV incidence in active-duty U.S. military was 21 cases per 100,000 service members, slightly higher than that of the general U.S. population, which was approximately 13.9 per 100.000 [21].

Between 1990 and 2024, the Department of Defense conducted over 46 million HIV screening tests, reflecting an extensive and ongoing surveillance effort aimed at early detection and prevention. A total of 1,581 active-duty service members were diagnosed with HIV between January 2017 and June 2022, with 62% remaining on active duty following their diagnosis [22].

These trends are particularly relevant given the global mobility of U.S. forces and their deployment in diverse environments, often under operational stress or during humanitarian missions, which may complicate prevention efforts [23].

In sub-Saharan Africa, HIV/AIDS has disproportionately impacted military personnel compared to civilians. This increased vulnerability is linked to demographic factors- mostly young, sexually active men- and the specific conditions of military service, such as extended time away from home, deployment to unstable regions, and social dynamics that encourage risky sexual behavior [15,16,24].

In 2014, Lloyd et al. reported that the prevalence of HIV among military men from sub-Saharan Africa and other low-income settings was notably higher compared with civilian men of reproductive age, and even higher among longer-serving service members [25]. In 2024, Grillo et. al revealed that military members were frequently involved in dense HIV transmission networks, alongside the civilian population and female sex workers [26].

The Perspective on HIV/AIDS in the Romanian Army

Military personnel infected with HIV but without any functional deficiency (e.g., those who are asymptomatic, experiencing acute retroviral syndrome, or presenting with generalized persistent lymphadenopathy) or who have only low functional impairment (e.g., clinical manifestations due to HIV infection; constitutional symptoms; herpes zoster; idiopathic thrombocytopenic purpura; or peripheral neuropathy) are not classified as having a disability and are allowed to continue performing their military duties [27].

Risk Factors for HIV in the Military

Military populations are considered to be at an elevated risk for acquiring HIV infection [12] due to exposure to a multitude of risk factors. The composition of military forces- mostly young, sexually active males- places them in a higher-risk demographic compared to the general population [25]. Frequent deployments that often result in extended separation from stable partners may further increase the tendency to engage in unsafe sexual practices [28]. The mobility of military troops and exposure of personnel to high-prevalence settings also contribute to this risk [11, 26].

Sexual risk behavior is an essential driver of transmission. In 2015, Hakre et al. reported that among HIV seroconverters in the U.S. Army between 2012 and 2014, most reported multiple sexual partners, inconsistent condom usage, and casual sexual contact or anonymous partners in the year before diagnosis [10].

A culture of masculinity and peer pressure has been reported to contribute to the encouragement of sexual risk-taking behaviors among military personnel [29], influencing HIV-related practices and increasing vulnerability to infection [30].

Tran et al. reported in 2019 that in the Armed Forces of the Republic of the Congo, alcohol consumption, commonly reported among active-duty soldiers, has also been shown to encourage risky sexual habits such as a reduction in condom usage; an increase in transactional sex and multiple sexual partners compared to the lower risk peers [31]. Similar patterns were reported on by Harbertson et al. in 2019, in the U.S. Marine Corps, where a reduction of condom use was associated with alcohol abuse or drug use to enhance sexual experiences [32].

Institutional barriers that may delay diagnosis, prevention, and linkage to healthcare within the military population include concerns over confidentiality and fear of stigma or professional consequences [33], furthering a decrease to essential social and medical care, such as ART [34].

HIV Prevention Strategies and Program Implementation in Military Settings

HIV epidemiology and prognosis have improved substantially due to the universal use of ART, the availability of medications that are more effective and better tolerated by patients [35], and the introduction of preventive measures such as pre-exposure prophylaxis (PrEP) [36]. With a timely diagnosis followed by early initiation of ART, the life expectancy of individuals living with HIV has significantly increased [37, 38].

The Department of Defense (DoD) in the United States of America offers the TRICARE program as part of its efforts to reduce the spread of HIV. This program includes a range of services aimed at both HIV prevention and care. Key initiatives include coverage for pre-exposure prophylaxis (PrEP), as well as promoting access to treatment options such as ART. Additionally, TRICARE provides counseling and support services, and it covers HIV testing for beneficiaries identified as being at risk for contracting the infection [23, 39].

Nonetheless, public health initiatives still encounter obstacles. Misconceptions about HIV transmission are prevalent among people of reproductive age in developing countries and represent a barrier to effective prevention efforts [40,41]. Promoting medical education and raising awareness around HIV-related stigma may have a positive impact on lowering risky sexual behaviors, particularly among military populations [42, 43].

The Department of Defense HIV/AIDS (DHAPP) of the United States of America implements an extensive HIV/AIDS prevention program with various strategies and interventions. These include index case HIV testing, periodic updates to military HIV policies, promotion of condoms, and facilitating access to them. DHAPP also conducts training to prevent stigma and discrimination related to HIV/AIDS [44].

In 2011, Singh and Banerjee conducted a survey among regimental officers regarding hiv prevention in the armed forces and found that there were difficulties in program implementation, especially in the promotion of condom use [45]. In 2015, Tran et al. reported that distributing free condoms to military personnel with improved packaging and a more pleasant scent led to an increase in usage among servicemembers, thereby enhancing efforts to prevent sexually transmitted infections within the military community [46].

Anastario et al. conducted in 2012 a pilot study in a military unit in Barbados, where a modified version of the Popular Opinion Leaders (POL) intervention was used. This intervention involved selecting and training Popular Opinion Leaders within the military personnel to promote conversations on condom use. As a result, there was a noticeable rise in condom use among military personnel after the intervention [47].

CONCLUSION

HIV/AIDS continues to pose a serious health challenge on a global scale, even as progress has been made in recent years. The prevalence of the disease remains a significant social and public health concern, with millions of individuals affected worldwide.

In military settings, targeted prevention strategies are particularly important due to the specific occupational and behavioral risks associated with service. Various armed forces have adopted structured programs aimed at limiting transmission, supporting personnel living with HIV/AIDS, and addressing stigma within military environments.

By focusing on education, encouraging risk-reduction behaviors, and ensuring access to services such as PrEP and ART, military institutions play a key role in HIV control. Sustained implementation of these measures can help transition HIV/AIDS from a widespread public health threat to a manageable chronic condition.

Abstract: Since February 24, 2022, military personnel of the Ukrainian Defense Forces have been resisting the military aggression of the Russian Federation. The fighting and the mobilization of men for military service complicated the well-being of Ukrainian families. The purpose of the article is to identify the relationship between the choice of coping strategies and post-traumatic stress disorder (PTSD) and maladaptation indicators in married and unmarried mobilized military personnel. Ukrainian Defense Forces military personnel (n=171 males, between 20 and 60 years of age) took part in this study. The "Strategic Approach to Coping Scale", "Mississippi Scale for Combat-Related Posttraumatic Stress Disorder", and "Disadaptation Express Questionnaire" were used. Correlation and exploratory factor analysis made it possible to identify the structure of coping strategies in mobilized servicemen with different family statuses and to determine the relationships between coping strategies, PTSD, and maladaptation indicators. The pre-war experience of using coping strategies by married and unmarried mobilized military personnel was not a sufficient barrier to the emergence of PTSD symptoms and maladaptation manifestations. Married and unmarried mobilized servicemen had a deficit structure of coping strategies characteristic of war.

Keywords: military personnel; coping strategies; PTSD; family; combat stress; mental health; mobilized soldiers; Russian-Ukrainian war

INTRODUCTION

The large-scale war in Ukraine, which began on 24.02.2022, has exacerbated the problem of mobilizing civilians and preparing military personnel to participate in hostilities to protect the sovereignty and lives of Ukrainians [1]. However, mobilization for military service has also complicated the well-being of families, who are forced to overcome problems arising from threats to the health and lives of family members, changes in family lifestyle, and everyday difficulties on their own, without men/women. This was also due to military actions on the territory of the country: experiencing threats of air raids, loss of housing, forced displacement, distance learning for children and their permanent stay at home, remote work or its absence, etc. [2,3]. These circumstances were factors that destroyed families, as well as additional stress for military personnel who, while defending their country, cannot protect and preserve their families.

Coping with potentially traumatic situations, including combat stress, involves the use of coping mechanisms and stress management strategies [4]. One of the models of stress management is the "Multiaxial Model of Coping", which comprises three axes: active–passive, prosocial–antisocial, and direct–indirect [5]. These axes represent dimensions of general coping strategies that allow for broader application across individualistic and collectivist cultures. The model assumes that active and avoidant strategies are not socially indifferent, and ignoring this fact may lead to a misinterpretation of their effects [6]. Prosocial coping involves strategies that positively utilize social resources. Antisocial coping includes behaviors that, while

satisfying the individual's needs, can be detrimental to others [7]. Aggressive coping is also effective as long as it does not become outright antisocial. Antisocial coping does not denote psychopathological behaviors, but rather coping methods that can be potentially harmful to others, involving the use of others or even exploiting them for personal gain [8].

Research has detailed the negative impact of combat deployments on service members and their families, the devastating effects of maladaptation and post-traumatic stress disorder (PTSD) symptoms on families, including violence against spouses and children [9,10]. PTSD couples reported clinically significant levels of relationship distress several times more frequently than comparison couples, both for general distress and across all specific problem areas (e.g., aggressive behavior, quality of leisure time together, sexual functioning, conflicts about finances and child rearing) [11]. Another study found that greater unit support, marital satisfaction, and psychological hardiness were associated with less anger, anxiety, depression, and PTSD symptomatology in soldiers [12]. The positive effects of intimate partner [13] and unit support reduced negative emotionality and traumatic stress only for veterans with less severe combat experiences [14].

However, the conducted studies did not examine the features of PTSD manifestations and maladaptation to the choice of coping strategies of mobilized servicemen with different family statuses. For such people, military service was not their own choice, and they were forced to adapt their civilian traumatic experience to overcome the effects of combat stressors and wartime stress factors.

The purpose of the article was to identify the relationship between the choice of coping strategies and indicators of post-traumatic stress disorder and maladaptation in married and unmarried mobilized military personnel.

MATERIALS AND METHODS

Study design and participants

This study was an exploratory descriptive study. All participants provided their informed consent for inclusion before engaging in the study. Ukrainian Defense Forces military personnel (n=171 males, aged 20 to 60 years, with a mean age of 41.84±6.49 years) participated in this study. The participants included 71% privates and 29% non-commissioned officers, all of whom participated in the Russian-Ukrainian war and had combat experience ranging from 6 to 10 months (8.75±2.58 months). Before the war, 62% of the participants had urban origins, while 38% had rural origins; 24% had completed secondary education, 57% had completed secondary specialized education, and 19% had attained higher education. The military personnel were sent to the rehabilitation center from combat positions to partake in a psychological recovery program lasting 14 days [15]. Two groups were formed to conduct the study: group 1 included 76 unmarried participants, while group 2 consisted of 95 married mobilized military personnel. The participants were identified based on various manifestations of acute stress reactions, significant negative experiences—including signs of depression and suicidal ideation—presence of PTSD symptoms, sleep problems (more than 50%), somatic complaints (more than 80%), and wounds and contusions (more than 75%); they also faced difficulties in returning to combat missions due to the consequences of illness, injury, and wounds. Female military personnel were excluded from this study because less than 0.5% of female combatants participated throughout the program period. Officers were also not included in the study due to their small number in the psychological recovery program (less than 1%). Participants were randomly selected for the study.

Ethical approval

The study was conducted in accordance with the Declaration of Helsinki and was approved by the Institutional Ethics Committee of the National Academy of the National Guard of Ukraine, Kharkiv, Ukraine (protocol code 2024/12, dated September 24, 2024).

Instruments

To determine the relationship between the choice of coping strategies and indicators of PTSD and maladaptation in mobilized military personnel, the "Strategic Approach to Coping Scale" (SACS), "Mississippi Scale for Combat-Related Posttraumatic Stress Disorder" (MSCRPTSD), and "Disadaptation Express Questionnaire" (DEQ) were used.

The SACS was used to determine coping strategies and behavior patterns of military personnel to overcome stressful situations, adapted into Ukrainian [16,17]. The SACS consists of 54 statements, the answers to which were given on a 5-point Likert scale (Cronbach's α = 0.846). The scale allowed for the choice of coping strategies (behavior models) such as "Assertive Actions" (Cronbach's α = 0.627), "Social Joining" (Cronbach's α = 0.736), "Seeking Social Support" (Cronbach's α = 0.746), "Cautious Actions" (Cronbach's α = 0.676), "Instinctive Actions" (Cronbach's α = 0.691), "Avoidance" (Cronbach's α = 0.669), "Indirect Actions" (Cronbach's α = 0.654), "Antisocial Actions" (Cronbach's α = 0.687), and "Aggressive Actions" (Cronbach's α = 0.724). The results were analyzed by comparing the data on the degree of expression (low, medium, high) of a specific person's coping behavior for each subscale with the average values of the coping stress models.

The MSCRPTSD [18] was used to diagnose PTSD in military personnel on missions in the war zone, adapted into Ukrainian [17, 19]. The scale consists of 35 statements (4 subsets), the answers to which were given on a 5-point Likert scale (Cronbach's α = 0.88). Subset 1 (11 statements) describes the symptoms of the "intrusion" group when the traumatic event is constantly repeated in the experience in one (or more) ways. Subset 2 (11 statements) relates to the symptoms of the "avoidance" group when there is a constant avoidance of stimuli associated with trauma, blocking of emotional reactions, and numbness, which was not observed before the trauma. Subset 3 (8 statements) describes the symptoms of “excitability” when persistent symptoms of arousal increase that were not observed before the injury. Subset 4 (5 statements) describes symptoms associated with guilt and suicidal tendencies. Despite the grouping of statements into 4 subsets, one general indicator was calculated taking into account the conversion of the answer into a score for direct and inverse statements, reflecting the severity of PTSD symptoms (range from 35 to 175 points, where 35-80 points is a variant of the norm; 81-114 points - separate symptoms of PTSD; 115-175 points - clinical manifestations of PTSD, a psychiatric examination and inpatient examination were recommended).

The DEQ was used to identify signs of a violation of the adaptability of the soldier’s personality: violation of the regulatory function of the emotional-volitional sphere and self-esteem; lack of prospects for continuing life and the ability to overcome life’s difficulties (probability of committing suicidal attempts); loss of moral convictions, the likelihood of committing addictive and delinquent acts; loss of communicative potential (comradely support, reduced ability to accept the help of one’s team) [19]. The DEQ consists of 45 statements included in 5 subscales (Cronbach’s α = 0.848): “Sincerity of answers” (Cronbach’s α = 0.719), “Violation of behavioral regulation” (Cronbach’s α = 0.736), “Probability of committing suicide attempts” (Cronbach’s α = 0.743), “Violation of moral normativity” (Cronbach’s α = 0.702), and “Loss of communicative potential” (Cronbach’s α = 0.709). Each positive response was worth 1 point, and each negative 0 points. The overall DEQ scale was calculated as the sum of scores on 4 scales (values on the “Sincerity of answers” scale were not included). The results of the overall DEQ scale were evaluated as follows: 1-10 points - high adaptation to combat operations, sufficient tolerance to adverse mental and physical stress, including under conditions of severe combat stress; 11-14 points - average adaptation, unstable level of performance, especially in combat conditions; 15 points or more - low adaptation (distress and adjustment disorders) that does not meet the requirements for soldiers in combat conditions.

Information on the implementation of a formal translation or back-translation protocol for SACS, MSCR-PTSD, and DEQ is unavailable. The authors of the article did not pilot test or validate the design of the psychodiagnostic instrument used in this study; we used data from the aforementioned Ukrainian sources. We are not aware of any published or internal references that describe the psychometric properties of the Ukrainian versions of these instruments in detail.

Statistical Analysis

The study was conducted in two stages. At the first stage, the use of correlation analysis allowed us to determine the relationships between the indicators of coping strategies, PTSD, and maladaptation in unmarried (group 1) and married (group 2) participants. At the second stage of the study, the indicators of coping strategies, PTSD, and maladaptation were compared in two participant groups. For the data presented, basic descriptive statistics were used (arithmetical mean M, standard deviation SD). The reliability of differences in the results of the mean values in two interrelated groups was determined using Student’s t-test. For the assessment of the statistical significance of differences, we used the level of significance from $p = 0.05$ to $p = 0.001$. No correction for multiple comparisons was applied.

Exploratory factor analysis was used to determine the structure of coping strategies in each participant’s group. Exploratory factor analysis of matrices was carried out using the extraction method (principal component analysis) and the rotation method (Varimax with Kaiser normalization). We did not perform the Kaiser-Meyer-Olkin (KMO) statistic and Bartlett’s test of sphericity for each group. Correlation analysis allowed us to determine the relationships between the identified factors in married and unmarried participants. The study results were statistically analyzed using SPSS 22.0 (IBM, Armonk, NY, USA).

RESULTS

Tables 1–2 present the results of the correlation relationship between the indicators SACS, MSCRPTSD, and DEQ scales by the group 1 and group 2 participants.

Table 3 presents the results of the coping strategies by the group 1 and group 2 participants.

Tables 4–5 present the exploratory factor analysis results of the coping strategies structure by the group 1 and group 2 participants.

Tables 6–7 present the correlation results between the factor structure of coping strategies and indicators of PTSD and maladaptation by the group 1 and group 2 participants.

DISCUSSION

At the first stage of the study, the use of correlation analysis allowed us to determine the relationships between coping strategies and indicators of PTSD, maladaptation in mobilized military personnel with different family statuses. Thus, productive coping "Assertive actions" (p = 0.01), "Social joining" (p = 0.01), and "Seeking social support" (p = 0.01) were associated with lower indicators of PTSD and maladaptation only in married participants (group 2). Such unproductive coping as "Instinctive actions" (p = 0.05), "Avoidance" (p = 0.05), "Indirect actions" (p = 0.05), "Antisocial actions" (p = 0.05) had relationships with the indicators of PTSD and maladaptation only in unmarried participants (group 1). The coping "Aggressive actions" (p = 0.01) was interrelated with the PTSD and maladaptation indicators in both groups of participants. The obtained results allow us to assume that such civilian experience as life in marriage influenced some features of the choice of coping strategies that determine the ability of mobilized servicemen to withstand combat stress factors. Similar studies showed that problem-solving coping reduced PTSD symptoms, while coping strategies aimed at avoiding stressful situations increased them [20]. Our results showed that this relationship is also be influenced by the family status of a serviceman.

As previously noted, social relationships such as intimate partners and military unit support reduced PTSD symptoms and negative emotionality and had a positive impact on military personnel's well-being [14]. In our study, we assumed the possibility of other variants of these relationships: the maladaptation indicators could have been by receiving specific social assistance ("Seeking social support"), and the symptoms of PTSD were could reduced while maintaining or restoring the ability to engage in general activity ("Social joining"). We found that in group 2, the indicators of choosing such coping strategies as "Social joining" and "Seeking social support" were the highest among all coping strategies, and they differed from the indicators of group 1 (p = 0.05 for both values).

In the second stage of the study, exploratory factor analysis and correlation analysis were used to identify the tentative structure of coping strategies among mobilized military personnel with different family statuses, as well as to determine the relationship between coping strategies and indicators of PTSD and maladaptation.

In group 1, the identified tentative three-factor structure of coping strategies described 70.72% of the variance of features. The factor 1 content was determined by the coping strategies "Seeking social support," "Social joining," and "Cautious actions." This factor was associated with the involvement of additional external resources. Perhaps, when asking for assistance, the group 1 participants were afraid of making a mistake, which could become an additional source of stress. This factor was designated as "Limited search for socially significant assistance." The factor 2 content was determined by the coping strategies "Antisocial actions", "Indirect actions", and "Aggressive actions". These coping strategies were associated with the abuse of actions to create one's superiority over others, to create conditions for using the resources of colleagues for one's purposes. This factor was designated as "Destructive methods of gaining an advantage over others". The positive pole of factor 3 was determined by the coping strategies "Assertive actions", and the negative pole "Avoidance". These coping strategies were associated with one's confidence and readiness to take responsibility. However, unlike assertive actions in group 2, where they may have been part of the interaction to overcome the consequences of stress factors. In group 1 assertive actions were possibly a component of self-affirmation. This factor was designated "Self-affirmation as a demonstration of decent behavior".

It should be noted that the group 1 participants showed a tendency where destructive ways of gaining an advantage over others rather increased mental trauma than contributed to protection from the effects of stress factors. In this group, the factor "Self-affirmation as a demonstration of decent behavior" to a certain extent contributed to the reduction of "Disruption of behavioral regulation" (p = 0.05) and "Likelihood of committing suicide attempts" (p = 0.05). Indeed, the self-confidence and assertiveness that characterized the participants in this group may have been characteristics that allowed them to control themselves in a stressful situation.

In group 2, the identified tentative three-factor structure of coping strategies described 69.43% of the variance in features. The content of factor 1 included the coping strategy "Seeking social support," "Social joining," and "Assertive actions." These strategies emphasized the importance of seeking external resources while considering the interests of fellow soldiers to mitigate the effects of combat stress factors. We referred to this factor as "Socially significant methods of attracting external resources." The content of factor 2 was determined by the coping strategy "Indirect actions" and "Antisocial actions". This factor was designated as "Socially inconsistent methods of attracting external resources" and had a statistically significant negative relationship with the consequences of the stress experienced: PTSD indicators (p = 0.01) and all maladaptation indicators (p = 0.01). Factor 3 was associated with the coping strategy "Instinctive actions" and "Avoidance". This factor was designated as "Uncertainty in one's resources and careful attitude towards them". The main goal of the described factor structure of coping strategies in group 2 was associated with to attract additional resources and avoid unfavorable circumstances.

In studies that examined the factor structure of coping strategies, three main factors have often been identified: problem-focused coping, getting social support, and avoidance [21,22]. However, we found that all mobilized servicemen had a deficit structure of coping strategies. Moreover, married servicemen had a desire to obtain additional external resources by any means to overcome the effects of combat stress factors, as well as a careful attitude towards their resources. It can be assumed that married servicemen were more oriented towards interaction to overcome stressful situations, while unmarried servicemen were forced to rely more on their strength.

It is a common assertion that the effectiveness of stress attenuation is limited because it is often not possible to avoid stressors, and avoiding or minimizing stress can lead individuals to miss opportunities for performance and growth. Thus, during stressful situations, a more efficacious approach is to optimize stress responses (i.e., promote adaptive, approach-motivated responses) [23]. Another study concluded that an avoidant-focused coping style acts as a vulnerability factor for PTSD symptoms, whereas hardiness acts as a resilience factor against symptom development [24]. Thus, when interpreting coping strategies such as "Cautious actions" and "Instinctive actions", it is necessary to take into account their role in the overall structure of coping and how personal resources for coping relate to the strength of stressful impacts. Our results partially confirm the conclusions that: (1) a robust latent variable named personal resources (indicated by social support, unit cohesion, and trait resilience) was negatively associated with PTSD severity; (2) personal resources were negatively associated with negative posttraumatic cognitions; (3) negative posttraumatic cognitions fully mediated the association between personal resources and PTSD severity [25].

Study limitations

This study certainly had limitations. 1) The study served as a generalization of experiences from the rehabilitation center focused on the psychological recovery of military personnel following participation in hostilities. This significantly influenced the amount of available empirical data (including sample size and psychodiagnostic survey methods), the study's structure, and the mathematical processing methods used. 2) The research was exploratory, aimed at generalizing the outcomes of surveys of military personnel involved in the psychological recovery program, as well as identifying potential hidden resources and methods for preventing PTSD and maladjustment. 3) Information on the implementation of a formal translation or back-translation protocol for SACS, MSCR-PTSD, and DEQ is unavailable. The authors of the article did not pilot test or validate the design of the psychodiagnostic instrument used in this study; we used data from the Ukrainian sources. We are not aware of any published or internal references that describe the psychometric properties of the Ukrainian versions of these instruments in detail. 4) The risk of false positive results was increased by the fact that no correction for multiple comparisons was applied. 5) Data on resources for building resilience against combat stress factors was limited among mobilized military personnel who did not choose military careers and received very brief training. 6) Existing data on family support for servicemen relates to scenarios where families are safe, a situation not observed in Ukraine, creating an ambivalent role for the family that can serve as both a source of anxiety and a resource. 7) The research was conducted on a sample of servicemen who participated in the psychological recovery program, specifically those exhibiting signs of mental and physical exhaustion, PTSD symptoms, and maladjustment. Consequently, the results related to the characteristics of coping structure deficits in both established variants—typical for married and single mobilized servicemen—should be specifically attributed to the corresponding samples. As a result, it is inappropriate to extend the findings of this study to servicemen who cope more effectively with the impact of combat stress. 8) The results obtained possess low practical value (Cohen's d); however, they allow us to formulate valuable hypotheses for further research. For example, PTSD prevention may be linked not only to direct family support but also to shared life experiences such as joint problem solving, which remain relevant even in the absence of direct family support, highlighting its value. Additionally, an intriguing hypothesis is the assessment of individual coping: its position within the overall coping strategy framework (which may exhibit signs of collective or individual culture) and the general nature of this structure concerning the situation (for instance, a deficiency in the overall structure indicating a reliance on external assistance). 9) Female military personnel were excluded from this study because less than 0.5% of female combatants participated throughout the duration of the psychological recovery program. 10) The participant sample consisted solely of enlisted military personnel and sergeants; officers did not take part in this study. 11) This study faced limitations due to the brief duration of the psychological recovery program and the need to avoid overloading participants with additional activities that did not align with the program's objectives, which limited the application of research methods and the repeatability of the survey, among other factors. Finally, the current study was constrained by the absence of an active comparison condition and a longitudinal follow-up. Thus, by summarizing some of the outcomes from the rehabilitation center's work on the psychological recovery of military personnel following military operations, we aimed to attract the scientific community's attention to addressing new urgent challenges in military medicine and psychology, particularly in the unique area of psychological support for mobilized military personnel.

CONCLUSION

The pre-war experience of using coping strategies by married and unmarried mobilized military personnel was a rather weak preventive measure for counteracting combat stressors, and not a sufficient barrier to the emergence of PTSD symptoms and maladaptation manifestations Assertive actions could be associated as a preventive factor for the negative consequences of combat stress only in married military personnel. Perhaps this was due to their structure of coping strategies, in which assertive actions were an integral part of interaction, while in unmarried servicemen it was self-affirmation. The creation of a wide range of social relationships had a positive impact on the preventive power of social interaction, which helped to overcome the consequences of PTSD and social maladaptation manifestations for both groups of mobilized military personnel. Aggressive actions, which became a source of additional stress and a method of responding to stress, were linked to higher PTSD scores.

Psychological support of the family among married mobilized servicemen was associated with the formation of resilience to the action of combat stress factors. In addition, compatible actions of married servicemen in stressful situations due to feedback formed an adequate stress response, reduced the likelihood of meta-experiences. Unmarried mobilized servicemen did not have family experience, so their coping strategies mainly came down to reacting and individual resilience to combat stress factors.

Married and unmarried mobilized servicemen had a deficit structure of coping strategies characteristic of war. They realized that their resilience to the effects of combat stress factors depended on the possibility of receiving help from others. And if married mobilized servicemen were more inclined to exercise caution when spending their resources, then unmarried servicemen tried to use self-assertive behavior as a method to raise their authority and thus attract additional external resources.

Abstract: The rise of antimicrobial resistance poses a significant challenge to global health. This study investigates the antimicrobial properties of Taraxacum officinale and Chelidonium majus. Taraxacum officinale, commonly known as dandelion, has been utilized for centuries in traditional medicine for its various therapeutic benefits, including treating cholecystitis, enhancing hepatic function, regulating blood pressure and cholesterol levels, and exhibiting diuretic effects. Additionally, research has indicated that infusions derived from this plant offer favorable outcomes in managing renal diseases. This study aims to assess the antimicrobial activity of extracts from Taraxacum officinale and Chelidonium majus employing qualitative screening, quantitative determination, and in vitro evaluation of anti-biofilm properties. In vitro evaluation of the antibiofilm activity of plant products revealed their ability to inhibit the development of biofilms on inert substrate; plant extracts of C. majus were found to inhibit biofilm formation in all bacterial strains tested, while tincture of T. officinale showed very good activity on gram-negative and fungal strains. The results obtained are promising, supporting further research into the biochemical characteristics of these extracts in order to formulate strategies for the control of bacterial and fungal infections in humans.

Keywords: extracts, antimicrobial effect, antibiofilm, Taraxacum officinale, Chelidonium majus

INTRODUCTION

The modern era of antimicrobial chemotherapeutics began with the discovery of sulfonamides and penicillin, and in the following decades the spectrum of antimicrobial substances was broadened by the discovery of new active substances capable of preventing and/or treating infections caused by pathogenic microorganisms. Thus, the introduction of antibiotics was a crucial moment that underpinned the saving of millions of patients, while at the same time leading to significant advances in medicine [1].

However, less than a decade after the clinical use of antibiotics, as a result of inappropriate prescribing or overuse of antibiotics both in humans and in veterinary and zootechnical medicine, without certainty of the infectious agent determined by laboratory tests or to promote animal husbandry [2], the gains from the development of this treatment are threatened by increasing rates of pathogen resistance to antibiotics, now leading to the Antimicrobial Resistance Crisis (AMR) [3].

The global increase in the incidence of infectious diseases that can no longer be eradicated with the substances developed to date represents the evolving response of microorganisms to the widespread administration of antibiotics. It has been declared by multiple organizations, such as the World Health Organization (WHO),

to be a public health problem of concern. Therefore, the AMR crisis has led to the need to investigate and discover new potential antimicrobial agents [4,5,6].

A new research direction is to exploit the antimicrobial properties of large varieties of medicinal plants, which represent a natural reservoir providing many compounds useful in the fight against multidrug-resistant microorganisms [7,8].

Taraxacum officinale (dandelion), is a medicinal plant that has been used for centuries for its benefits in the treatment of conditions such as cholecystitis, improving hepatic function, lowering blood pressure and blood cholesterol levels, or for its diuretic effect. In addition, studies in the literature have shown that infusions made from this plant have beneficial effects on renal diseases [8].

Chelidonium majus (celandine), one of the oldest and most widely used plants in traditional medicine, presents manyfold benefits, being often used in the treatment of eczema and condyloma caused by Human Papilloma Virus (HPV) infection, hepatic and gastric diseases, as well as having anti-inflammatory and analgesic effects. [9,10,11,12,13,14,15].

The aim of this work is to study the antimicrobial activity of extracts of Taraxacum officinale (tincture), Chelidonium majus (tincture). The following objectives were proposed to achieve this aim: qualitative screening of the antimicrobial activity of plant extracts, quantitative determination of the antimicrobial activity of plant extracts and in vitro investigation of the anti-biofilm properties of plant extracts. [16,17,18].

MATERIALS AND METHODS

Two plant extracts were analyzed in this study: Taraxacum officinale (dandelion) tincture and Chelidonium majus (tumbleweed) tincture.

Reference microorganisms were tested, two gram-negative bacterial strains: Escherichia coli ATCC 25922 and Pseudomonas aeruginosa ATCC 27853, two gram-positive strains: Staphylococcus aureus ATCC 25923 and Enterococcus faecalis ATCC 29212 and one fungal strain: Candida albicans ATCC 10231, according the American Type Culture Collection.

Qualitative evaluation of plant extracts was carried out by the drop method on solid agar medium by adapting the diffusimetric antibiogram method. Technique is: a 5µl volume of each plant extract was dropped onto the surface of a Plate Count Agar (PCA), non seleciv medium, inoculated with a standardized microbial suspension obtained from the strain to be tested by the cloth seeding technique. Sensitivity to a particular plant extract can be observed by inhibition of microbial growth around the deposited droplet. Interpretation of results: antimicrobial activity of the extracts was determined by assessing the formation of an inhibition zone around the deposited extract droplet and measuring its diameter using a millimeter ruler.

Quantitative determination of the antimicrobial activity of plant extracts was carried out by the microdilution method in liquid medium. Principle of the method: in 96-well ELISA microplates with liquid culture medium, 1/100 diluted microbial suspensions of the test strains are inoculated with an initial density of 0.5 McFarland in a gradient of plant extract concentrations. Minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC) values are determined by drop seeding on agar medium the first 8 wells corresponding to 50%- 0.195% concentrations of each plant extract.

Interpretation of results: antimicrobial activity of the extracts was determined by evaluating the growth of microbial cultures on agar medium. The MIC value represents the concentration at which the plant extract inhibits the growth and multiplication of microorganisms, having a bacteriostatic effect, and the MBC value represents the concentration at which the plant extract has a lethal action on microorganisms, having a bactericidal effect.

Evaluation of the antibiofilm activity of plant extracts was tested by the 1% crystal violet microtitration method: following incubation of sterile 96-well ELISA microplates with liquid culture medium in which microbial suspensions are inoculated in a gradient of concentrations of the tested plant extracts, the in vitro antibiofilm activity of different concentrations of tinctures and alcoholic extracts is analyzed on the basis of absorbance values of the 1% crystal violet dye at 492 nm. Interpretation of the results: the antibiofilm activity of the plant extracts could be evaluated by determining the absorbance value from the spectrophotometric reading at 492 nm. The concentration of the plant extracts required to inhibit biofilm growth corresponds to the last well at which the absorbance value is less than half the absorbance value of the positive control corresponding to the same plant extract.

RESULTS

In this study we aimed to investigate the antimicrobial properties of some plant extracts of Taraxacum officinale (tincture) and Chelidonium majus (tincture). Qualitative evaluation of the antimicrobial activity of T. officinale plant extract determined an inhibition of microbial growth against E. faecalis ATCC 29212, P. aeruginosa ATCC 27853 and C. albicans ATCC 10231 strains, showing inhibition halo values of 9 mm, 8 mm with weak microbial growth within the microbial inhibition zone and 8 mm with the presence of a large number of colonies within the inhibition halo, respectively. Resistance to the action of the plant extract was recorded for strains of S. aureus ATCC 25923 and E. coli ATCC 25922, with the presence of T. officinale tincture not inhibiting their microbial growth.

Microbial growth of the fungal strain was inhibited in the presence of the plant extract from C. majus, resulting in an inhibition zone value of 7 mm. The same growth inhibition zone diameter was also recorded for the E.coli strain ATCC 25922, and a value of 11 mm was observed for the gram-positive strain E. faecalis ATCC 29212 (Table 1). This extract showed no antimicrobial activity against S. aureus ATCC 25923 and P. aeruginosa ATCC 27853 strains.

The qualitative determination study of the antimicrobial activity of S. marianum tincture on reference strains reveals that on both gram-negative strains, E. coli ATCC 25922 and P. aeruginosa ATCC 27853, and fungal strain, C. albicans ATCC 10231, the plant extract showed no antimicrobial activity (Table I). Inhibition of microbial growth could however be observed for the gram-positive strains S. aureus ATCC 25923 and E. faecalis ATCC 29212, with growth inhibition zone values of 9 mm and 8 mm respectively.

Table 1. - Quality determination of antimicrobial activity.

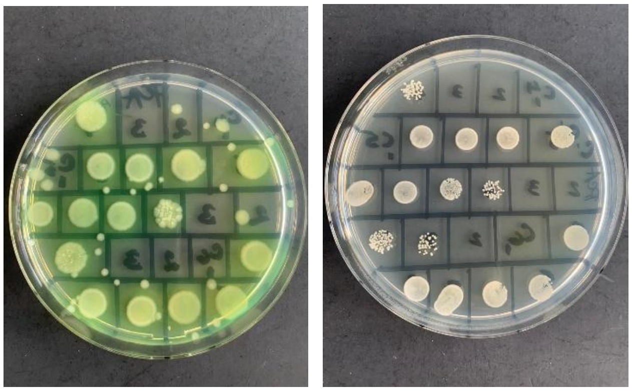
Strain tested	**Growth inhibition zone diameter (mm) and CMI**					
	***T. officinale* (tincture)**	**CMI**	**Interpretation**	***C. majus* (tincture)**	**CMI**	**Interpretation**
S. aureus ATCC 25923	0	N/A	resistant	0	N/A	resistant
E. faecalis ATCC 29212	9[1]	52µg/ µL	sensitive	1[1]	4298 µg/ µL	intermediate
E. coli ATCC 25922	0	N/A	resistant	7[1]	87 µg/ µL	sensitive
P. aeruginosa ATCC 27853	8[1]	66µg/ µL	sensitive	0	N/A	resistant
C. albicans ATCC 10231	8[2]	66µg/ µL	sensitive	7[1]	87 µg/ µL	sensitive

Legend: [1]weak/slight microbial growth within the inhibition zone. [2]presence of a large number of colonies within the inhibition zone.

Formula: $CMI=Q/V$ $Q=10000\mu L$ $V=\pi R^2 G$ (1)

The method of quantitative determination of the antimicrobial activity allowed to highlight the concentrations of the plant extracts at which the growth and development of the tested reference strains are inhibited, as well as the concentrations determining the bactericidal action. (Fig. 1)

Figure_1 - Results of antimicrobial activity testing: Agarized, drop-seeded medium from 96-well microplates with strains of *S. aureus, E. faecalis, E. coli, P. aeruginosa* and *C. albicans* after incubation for 18-24h at 37ºC



The plant extract of T. officinale shows a strong inhibitory effect on gram-negative P. aeruginosa ATCC 27853 and fungal strains, the bacteriostatic effect being achieved at a concentration of 3.13%, while on gram-positive strains and E. coli ATCC 25922, the concentration of the plant extract required to inhibit microbial growth is 12.5-25%. On gram-negative strains and E. faecalis strain ATCC 29212, the 12.5% concentration of C. majus extract has a bacteriostatic effect, thus a medium inhibitory effect was recorded, but a weak and a strong inhibitory effect of this extract was observed on C. albicans ATCC 10231 and S. aureus ATCC 25923 strains, with MIC values of 50% and 3.13% respectively.

The tinctures tested in the study showed lethal action on the reference microbial strains at an average concentration of 20.8%. For the plant extract of T. officinale, a concentration of 12.5% was required for bactericidal effect on S. aureus ATCC 25923, E. coli ATCC 25922 and C. albicans ATCC 10231 strains, and for E. faecalis ATCC 29212 and P. aeruginosa ATCC 27853, concentrations of 50% and 6.25%, respectively, were required. In the presence of C. majus tincture, the lowest CMB value recorded was 6.25% for S. aureus strain ATCC 25923. Bactericidal action on E. faecalis ATCC 29212 and P. aeruginosa ATCC 27853 strains was observed at a concentration of 12.5% of the plant extract, while concentrations of 25% and 50% were required for the gram-positive E. coli ATCC 25922 and fungal strains, respectively.

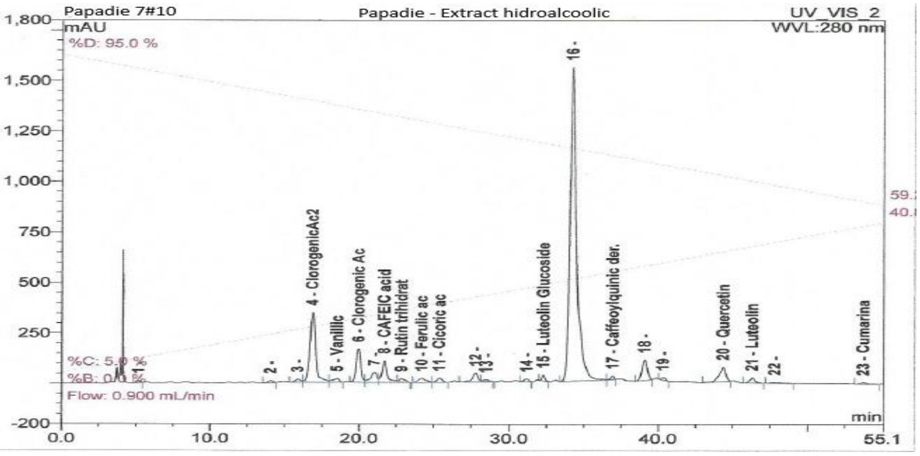
Analysis of spectrophotometric data revealed that T. officinale tincture shows little effect on Gram-positive strains, inhibiting biofilm growth at a concentration of 25%. The effect of this tincture was higher on gram-negative and fungal strains, with inhibition of biofilm growth observed at concentrations of 0.78%, 1.56% and 3.13% for C. albicans ATCC 10231, E. coli ATCC 25922 and P. aeruginosa ATCC 27853, respectively. The minimum concentration of C. majus tincture required to inhibit biofilm growth of C. albicans strain ATCC 10231 is 1.56%, while for E. faecalis ATCC 29212 and E. coli ATCC 25922 antibiofilm activity was achieved at a concentration of 12.5%, and for S. aureus ATCC 25923 and P. aeruginosa ATCC 27853 at 6.25%.

The chromatograms obtained in this study provide detailed information about the phytochemical composition of the extracts from Taraxacum officinale and Chelidonium majus. These analyses are essential for identifying the active compounds involved in the observed antimicrobial activity and for correlating them with the experimental results.

The attached figures present representative chromatograms for each extract, highlighting the main absorption peaks and specific compounds. This information contributes to a better understanding of the mechanisms through which the substances in the studied plants act against various microbial strains. The presence of active compounds is clearly demonstrated, supporting the qualitative and quantitative results obtained in the antimicrobial activity tests.

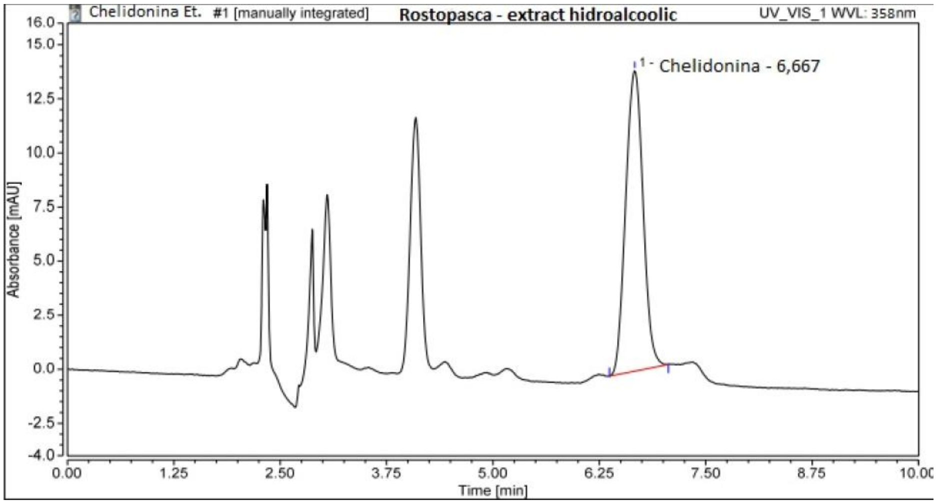
The chromatogram represents the analysis of hydroalcoholic extract of Taraxacum officinale, (Fig. 2) highlighting major phytochemical compounds such as luteolin glucoside (the main peak, indicating the dominant compound), caffeoyl derivatives, and luteolin. Additionally, chlorogenic acid and quercetin are present, known for their antioxidant and anti-inflammatory activities. This composition suggests a high therapeutic potential, supporting the antimicrobial activity observed in the study.

Figure_2 Chromatogram of hydroalcoholic extract of *Taraxacum officinalis*



The chromatogram analyzes a hydroalcoholic extract of Chelidonium majus (Fig. 3), highlighting chelidonine as the main compound (retention time 6.667 minutes), suggesting a high concentration. Chelidonine is an alkaloid known for its antimicrobial and antitumor properties. The smaller peaks indicate the presence of other alkaloids, such as sanguinarine or berberine.

Figure 3_ Chromatogram of hydroalcoholic extract of *Chelidonium majus*



DISCUSSION

The present study investigated the antimicrobial properties of plant extracts tinctures from Taraxacum officinale and Chelidonium majus. The qualitative and quantitative evaluations of antimicrobial activity revealed differential effects of these plant extracts on different strains, shedding light on their potential therapeutic applications.

Taraxacum officinale L. is a flowering herbaceous perennial plant of the Asteraceae family. Interest in researching the biochemical characteristics as well as the pharmacological properties of this species increased considerably in the 1950s, and numerous active substances have now been identified, including flavonoid compounds, phenolic acids such as cyclonic, chlorogenic and caffeic acid, alkaloids, and terpenes. In modern medicine, this plant is marketed and used as an herbal treatment to relieve symptoms of conditions such as arthritis, hepatic disorders and to suppress oxidative stress [17,18, 19,20,21,22,23]. Dandelion exhibits a diverse array of pharmacological effects, making it a valuable medicinal plant with potential therapeutic applications. The study by Trinh et al. 2020, reported that ethanol-based plant extract from T. officinale exhibits bactericidal effect on S. aureus strain ATCC 25923 at a concentration of 20 mg/ml [24]. T. officinale extract tested in the study by Sangeetha and Ezhilarasan 2016, showed lethal action on E. faecalis strain ATCC 29212 at a concentration of 200mg/mL [25]. The study by Shah et al. (2011) [26] showed that S. marianum extracts did not exhibit antimicrobial activity against the tested gram-negative strains E. coli ATCC 25922 and P. aeruginosa ATCC 27853.

Chelidonium majus is a medicinal plant belonging to the Papaveraceae family that is found in the wild flora of Europe, Asia, North America, as well as in some regions of Africa. It is widely used in traditional herbal medicine to treat conditions including biliary and hepatic dysfunction, jaundice and to relieve pain caused by edema. It has antidiuretic, spasmolytic, sedative, and antimicrobial properties. The dried aerial part of C. majus is an official medicine in the pharmacology of European countries, but it is necessary to administer it under the supervision of authorized medical personnel due to the presence of a rich concentration of isoquinoline alkaloids. [27,28,29,30,31]

The antimicrobial activity of the studied plant extracts varied significantly depending on the microbial strain and the type of extract used. For instance, T. officinale exhibited inhibition against E. faecalis and P. aeruginosa strains but not against S. aureus and E. coli. Similarly, C. majus showed inhibition against E. faecalis and C. albicans but not against S. aureus and P. aeruginosa. These findings suggest that the efficacy of plant extracts may be strain-specific, highlighting the importance of considering multiple strains in antimicrobial studies. [32,33,34,35]

The results of this study are consistent with some previous findings but differ from others. For example, the antimicrobial activity of T. officinale against S. aureus strain ATCC 25923 reported by Trinh et al. (2020) aligns with our findings, whereas Tunç et al. (2019) reported no antimicrobial activity against E. faecalis strain ATCC 29212, contradicting our observations. Such discrepancies may arise from variations in extraction methods, microbial strains, or growth conditions, emphasizing the need for standardized protocols and comprehensive strain selection in antimicrobial research.

The determination of MIC and bactericidal concentration provided insight into the potency of the plant extracts against different microbial strains. Higher MIC values were often observed for gram-negative bacteria compared to gram-positive bacteria and fungi. This differential susceptibility underscores the complex interplay between microbial cell wall structures and the mechanisms of action of plant compounds.

The ability of plant extracts to inhibit biofilm formation is of particular interest due to the role of biofilms in antimicrobial resistance. Our study demonstrated varying degrees of biofilm inhibition by the tested extracts, with some showing promising activity against both gram-positive and gram-negative bacteria as well as fungi. These findings suggest the potential of plant extracts as adjuncts in combating biofilm-associated infections.

Despite the valuable insights provided by this study, several limitations should be acknowledged. The use of reference strains may not fully represent the diversity of clinical isolates, warranting further investigations with clinically relevant strains. Moreover, elucidating the underlying mechanisms of antimicrobial activity and conducting in vivo studies are crucial steps toward clinical translation.

The chromatographic analysis of the hydroalcoholic extracts of Taraxacum officinale and Chelidonium majus revealed the presence of major bioactive compounds, each contributing to the specific therapeutic potential of the plant. The chromatogram of Taraxacum officinale indicated Luteolin glucoside as the main compound, known for its antioxidant and anti-inflammatory activities, alongside caffeoyl derivatives. For Chelidonium majus, chelidonine (retention time 6.667 minutes) was identified as the major compound, recognized for its antimicrobial and antitumor properties.

These results emphasize that each extract possesses a distinct phytochemical composition that may synergistically contribute to the observed antimicrobial activity. The identification of specific compounds through chromatographic analysis supports the understanding of the mechanisms of action of the extracts and justifies further investigations into their use in antimicrobial, antioxidant, and hepatoprotective treatments. This study underscores the diverse antimicrobial potential of plant extracts against a range of microbial pathogens. Further research focusing on standardization, mechanism of action, and clinical efficacy is warranted to harness the therapeutic benefits of these natural products effectively.

CONCLUSION

In this experimental work, the antimicrobial properties of two plant extracts of Taraxacum officinale (tincture) and Chelidonium majus (tincture) were studied on 5 reference bacterial strains, two gram-positive (Staphylococcus aureus ATCC 25923 and Enterococcus faecalis ATCC 29212), two gram-negative (Escherichia coli ATCC 25922 and Pseudomonas aeruginosa ATCC 27853) and one fungal strain, Candida albicans ATCC 10231.

Qualitative testing of antimicrobial activity revealed that the plant extracts inhibited the growth and development of the tested microbial strains.

Quantitative determinations of antimicrobial activity allowed the determination of the concentrations of plant extracts responsible for the bacteriostatic and bactericidal effect, and a higher sensitivity of microbial strains could be observed in the presence of tinctures.

In vitro evaluation of the antibiofilm activity of plant products revealed their ability to inhibit the development of biofilms on inert substrate; plant extracts of C. majus were found to inhibit biofilm formation in all bacterial strains tested, while tincture of T. officinale showed very good activity on gram-negative and fungal strains.

The results obtained are promising, supporting further research into the biochemical characteristics of these extracts in order to formulate strategies for the control of bacterial and fungal infections in humans.

Abstract: Introduction: Non-melanoma skin cancers (NMSC) represent a significant global public health burden, particularly in high-income countries. The increasing incidence of head and neck NMSC contributes to rising morbidity and necessitates multi-disciplinary management. Objectives: This study aims to evaluate the incidence, demographic distribution, histological subtypes, and seasonal variation of NMSC over a five-year period at a tertiary center in Romania. Materials and Methods: A retrospective observational study was conducted from January 2020 to December 2024, including 180 patients diagnosed and treated for malignant skin lesions. Data were extracted from clinical and histopathological records. Chi-square tests assessed seasonal distribution, and Mann-Whitney U tests compared lesion depth and surface area between demographic groups. Results: A total of 388 malignant lesions were recorded. Basal cell carcinoma (BCC) was the most common subtype (n = 168), followed by squamous cell carcinoma (SCC) (n = 25). Most patients resided in urban areas, particularly Bucharest. Males presented with significantly deeper lesions (mean: 1.5 mm) compared to females (mean: 1.25 mm; $p = 0.009$). Seasonal analysis revealed a significant variation in incidence, with the lowest number of cases in spring ($\chi^2 = 10.31$, $p = 0.016$). Conclusion: The incidence of malignant skin lesions increased from 2020 to 2023, followed by a decline in 2024. Seasonal and sex-related differences were observed, with the face being the most frequent site of involvement. While the sex distribution was relatively balanced, males exhibited significantly greater lesion depths compared to females.

Keywords: non-melanoma skin cancers; squamous cell carcinoma; basal cell carcinoma; seasonal variation; epidemiology; retrospective study; head and neck cancer; Romania

INTRODUCTION

Cutaneous malignancies accounts for most cancers across the world and they are primarily divided into melanoma (MSC) and non-melanoma (NMSC) skin cancers [1]. According to the Globocan (Global Cancer Observatory) 2022 data, non-melanoma skin cancer ranks as the fifth most commonly diagnosed cancer worldwide, with over 1.2 million new cases reported [2]. However, despite its high incidence, NMSC ranks only 22nd in terms of cancer-related mortality, highlighting the generally favorable prognosis of NMSC compared to other malignancies [2].

The incidence of head and neck MSC and NMSC is rising all over the world and can be the source of significant morbidity and mortality [3]. The necessity of a multidisciplinary team that includes dermatology, plastic and reconstructive surgery, medical and radiation oncology remains a financial problem in many countries, due to the comprehensive care that needs to be provided for patients with head and

neck cutaneous malignancies [3,4].

The vast majority of non-melanoma skin cancers include basal cell carcinoma (BCC), followed by squamous cell carcinoma (SCC), both showing a rapidly increasing trend in their incidence in the last years and a significant health burden in many countries [5,6]. Although the exact global incidence of these two is unknown, an overview of the last years carried out by World Health Organization concluded that BCC comprises about 80% of all NMSC, while SCC comprise about 20%, with a BCC to SCC ratio ranging from 2 to 4:1 [5,6]. While this is a classic agreed ratio, the recent studies suggest a possible changing in the pattern due to aging of the population, with equal numbers of SCC and BCC being treated in the future [6,7].

Multiple etiological risk factors related to the individual or the environment were studied for understanding the cause of NMSC, but the main driving carcinogen remains ultraviolet radiation (UVR) [5,6]. This explains why over 80% of these malignancies occur on the sun exposed skin of the head and neck (followed by the hands and forearms), with higher prevalence of BCCs in the nasal area, while SCCs are preferentially located on the auricle [5,8,9]. UVR are responsible for the induced dinucleotide mutations at pyrimidine bases, exhibiting strong transcription strand bias and also showing a high mutational burden with the mutant genes varying between BCCs and SCCs [6].

Although its mortality is low and it rarely results in metastatic disease, BCCs can cause significant health burden through his great morbidity, generated by the destructive local spread [9]. These tumors are slow growing but can, however, develop large, causing locally tissular destruction and spreading into vital structures such as the central nervous system or important blood vessels [10]. Traditionally, the five most commonly accepted histological subtypes of BCC, described by Lang and Maize, include superficial, nodular, micronodular, infiltrative and morpheaform or sclerosing BCC [10,11]. Of note, a particular form of BCC, called the basosquamous cell carcinoma (BSCC) or the metatypical BCC, may arguably be a SCC subtype, as it shows both basal cell and squamous cell cancer differentiation in a continuous fashion [10,11]. The metatypical BCC, together with morpheiform and infiltrative BCC belong to the aggressive-growth subsets, while the others are considered indolent-growth variants [11]. Regarding their epidemiology, in one large retrospective study on 1039 consecutive cases of BCC, the histological analysis demonstrated 21% were nodular, 17% superficial, 15% micronodular, 7% infiltrative and just 1% morpheic [12].

In contrast with basal cell carcinoma, the squamous cell carcinoma has metastatic potential, and when present, the general prognosis is rather poor due to the mortality associated with regional and nodal metastases [9]. It is the most common skin cancer after BCC and generally has a good prognosis, the overall metastasis rate varying from 1% to 4% [13]. There are several risk factors attributed with the regional metastatic potential, like a poor differentiation, a perineural invasion, the presence of recurrency, a depth of invasion greater than 6 mm or a size bigger than 2 cm [14]. The SCC typically develop in a progressive manner, beginning with premalignant lesion -actinic keratosis (AK)-to in situ SCC (Bowen's disease) and eventually to invasive squamous cell carcinoma [13]. Usually, only a small proportion of the precursors develop into invasive cutaneous SCC [13,15]. Despite that, the high mortality of the metastatic variant and the high frequency of SCC in general remain of great concern and represent a financial burden for the health care services, as it needs a close clinical surveillance for many years [15].

Unlike the BCC variants, where the biological behaviors show little significant difference, there are a wide histopathological subtype of SCCs which demonstrates not just microscopic differences, but also a very diverse clinical behaviors [16]. There are several histologic subtypes of SCC and each of them carry an important prognostic significance [16,17]. The generic type (the simplex or conventional) has the greatest risk of metastasis, followed by lobular (acantholytic), Bowenoid, spindle (pleomorphic)-all three with a similar risk- and the last, verrucous carcinomas, has the most favorable prognosis [16,17]. Another predicting cancer behavior in cutaneous squamous cell carcinoma are the histopathologic parameters, which stage tumors into four categories primary based on their nuclear pleomorphism [17]. According to Broder, the tumors can be well-differentiated (less than 25% undifferentiated cells), moderately- well differentiated (less than 50% undifferentiated), poor differentiated (less than 75% undifferentiated) and anaplastic or pleomorphic (more than 75% undifferentiated) [17].

Nevertheless, the spectrum of head and neck cutaneous malignancies ranges from fairly well-behaved tumors (most of the BCCs) to potentially very aggressive cancers with high metastatic rate (usually melanoma, but also some histologic types of SCC) [3]. Their increasing incidence, the necessity of a multidisciplinary team and the need of a well-developed early screening evenly distributed among countries and regions, make the topic current and highly important in the present context.

The aim of this paper is to present the incidence of non-melanoma skin cancers of the head and neck in a single tertiary center in a retrospective study, from 2020 to 2024. Also, we'll describe the correlation between malignancies and gender, age, type of cancer, and its dimensions, together with trends in their frequency. Understanding temporal trends and potential fluctuations in incidence is essential for effective healthcare planning and resource allocation. Seasonal patterns in skin cancer diagnoses suggest that environmental factors, such as ultraviolet exposure, may influence disease occurrence and warrant further investigation. Additionally, variations in lesion characteristics between different demographic groups, including sex and geographic location, highlight the importance of exploring underlying biological, behavioral, and healthcare access factors. Investigating these aspects can contribute to improved prevention strategies, early detection, and tailored treatment approaches for skin cancer patients.

MATERIALS AND METHODS

A retrospective observational study was conducted on a database of patients diagnosed and treated for malignant skin tumors at a tertiary care center in Romania between January 2020 and December 2024. Due to the COVID-19 pandemic, there is a notable gap in data collection between April 2020 and June 2021, during which clinical activity was significantly reduced. The goal was to assess demographic distribution, histological types, anatomical localization, and treatment patterns of skin cancer patients in Romania in the last 5 years. Data were extracted from the institution's electronic medical records and physical registries, curated by the dermatology department.

The patients were selected using the following inclusion criteria: Patients with a clinical diagnosis of a skin lesion suggestive of malignancy; Hospital admission (i.e., full inpatient hospitalization, not outpatient consultation or day-case admissions); Histopathological confirmation of a malignant skin tumor.

Exclusion criteria consists of: Benign skin lesions and suspected malignancies for which no biopsy was performed (e.g., due to patient refusal or other contraindications).

Following the application of the inclusion criteria, a total of 388 malignant non-melanoma skin lesions were identified across 180 patients. While most patients presented with an average of approximately 2–3 lesions, a small subset exhibited over 10 malignant lesions each. Although not all lesions underwent histopathological confirmation, those that were not biopsied shared highly similar macroscopic features with confirmed cases, allowing for a reliable clinical diagnosis based on visual assessment.

The dataset includes both male and female patients residing in Bucharest as well as in 19 other counties across Romania. All patients sought medical evaluation and treatment at the tertiary facility. Of the 180 eligible patients, 125 (69.4%) originated from urban areas, while 55 (30.6%) were from rural settings. Sex distribution was relatively balanced, with 52% of the cohort being female and 48% male. Patient ages ranged from 35 to 93 years, with a median age of 69 years for females and 71 years for males.

The standard clinical pathway involved an initial dermatologic evaluation, during which a provisional diagnosis was made based on the morphological characteristics of the lesion. Patients then underwent a biopsy for histopathological confirmation. Upon receiving the diagnostic result, patients returned for definitive treatment, which typically consisted of complete surgical excision or electrocauterization, depending on the lesion's type, size, and location.

The following variables were systematically collected for each patient: demographic information (including age, sex, and place of residence); clinical characteristics (lesion location, provisional clinical diagnosis, year and month of diagnosis); histopathological data (tumor type and size); and treatment details, specifically the definitive procedure performed—either surgical excision or electrocauterization—as well as the occurrence of recurrence or the need for re-excision.

All tissue specimens were processed and analyzed by board-certified pathologists within the same department, using standard hematoxylin-eosin (H&E) staining tech-niques.

Data base was created using Microsoft Excel 2019. Statistical analysis was per-formed using JASP 0.19.3 program. Statistical analyses included Chi-square tests to as-sess seasonal distribution differences and Mann-Whitney U tests to compare lesion depth and surface area between demographic subgroups.

RESULTS

When analyzing the annual incidence of malignant skin lesions, a progressive in-crease was observed over the first four years of the study period: 18 cases in 2020, 25 in 2021, 40 in 2022, and a peak of 63 cases in 2023. This upward trend was followed by a decline in 2024, with 34 cases recorded (Fig. 1). A linear regression analysis revealed an average annual increase of approximately 7 cases (slope = 7), with a coefficient of determination (R^2) of 0.64, suggesting a moderate correlation between time and case number. However, the trend did not reach statistical significance ($p = 0.244$), likely due to the limited number of years analyzed and the variability introduced by external factors such as the COVID-19 pandemic in 2020–2021, the post-pandemic rebound in 2023, and the subsequent decrease observed in 2024.

The average hospitalization duration remained relatively stable over the past five years, starting at 4.2 days in 2020, slightly increasing to 4.5 days in 2021, then gradually decreasing to 4.3 days in 2022, and further declining to 4.1 days in both 2023 and 2024 (Fig. 2). The longest hospital stay was recorded in 2020, lasting 19 days, while the shortest stays of 2 days were observed in 2023 and 2024.

Figure 1.The trend line of malignant skin lesions

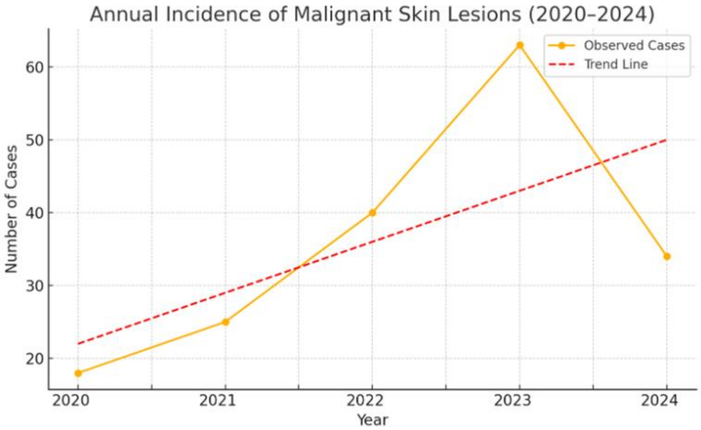

Figure 2. Evolution of the average hospitalization days (2020-2024)

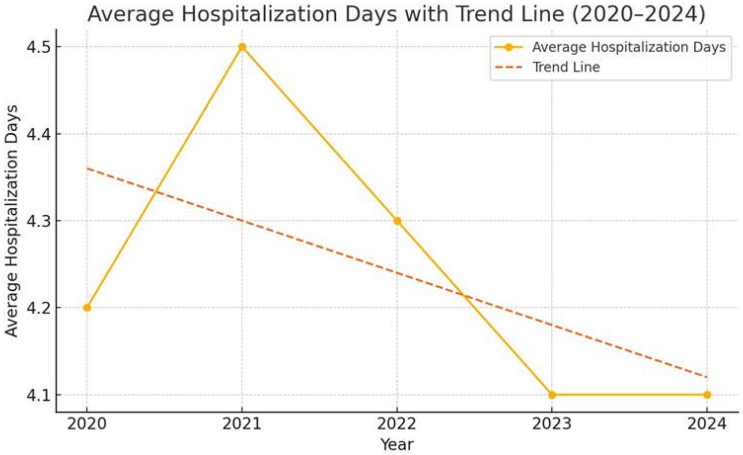

Of the 180 patients, 95 were residents of Bucharest, with the highest concentration coming from Sector 3 (n = 35) and Sector 4 (n = 32). Among patients from outside the capital, the neighboring counties of Ilfov (n = 16) and Giurgiu (n = 14) were the most represented.

When assessing seasonal distribution over the five-year period, the lowest incidence of diagnosed malignancies was observed in spring, with only 27 cases recorded. The other seasons showed relatively similar frequencies, with 47 cases in summer, 55 in autumn, and 51 in winter (Table 1, Fig. 3). In order to determine whether there is a significand difference between the observed frequencies and expected frequencies, we have applied the Chi-squeare test (χ^2). The test revealed a statistically significant difference in the seasonal distribution of skin cancer diagnoses ($\chi^2 = 10.31$, $p = 0.016$).

Table 1. Presentation period by month, year and season

Presentation period	2020	2021	2022	2023	2024	TOTAL	No. of cases per season

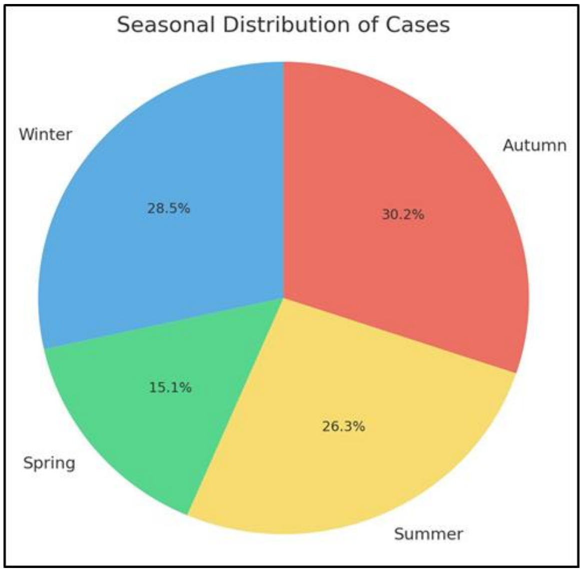
Figure 3. The percentage distribution of cases by season



The malignant skin lesions identified in this study were categorized into basal cell carcinoma (BCC), squamous cell carcinoma (SCC), and melanoma. Out of the total 388 lesions, 168 were classified as BCC (Fig. 4). Histopathological evaluation allowed for further subtyping of BCC cases. The nodular subtype was the most prevalent (n = 68), followed by the adenoid type (n = 43), superficial BCC (n = 26), and the infiltrative variant (n = 23). Rare subtypes included basosquamous, pigmented BCC, Pinkus fibroepithelioma, and infundibulocystic BCC, each represented by one or two cases. Additionally, a single case associated with Gorlin syndrome was documented. Notably, no cases of micronodular BCC were observed (Fig. 5). Regarding squamous cell carcinoma, a total of 25 cases were identified. The majority were well-differentiated SCCs (n = 16), followed by moderately differentiated SCCs (n = 8) and poorly differentiated SCCs (n = 3). No anaplastic SCCs were detected during the study period.

Figure 4. Distribution of non-melanoma skin cancers cases

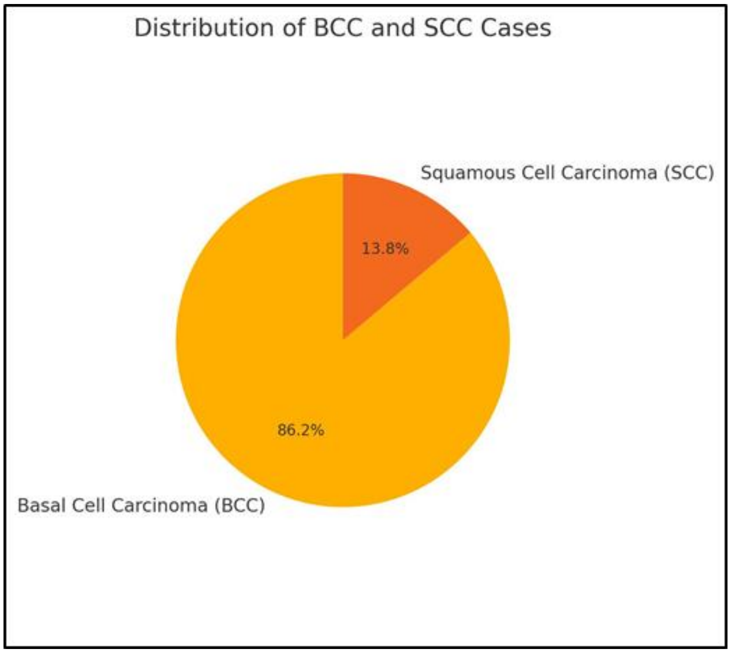


Figure 5. The incidence of histological subtypes of BCC

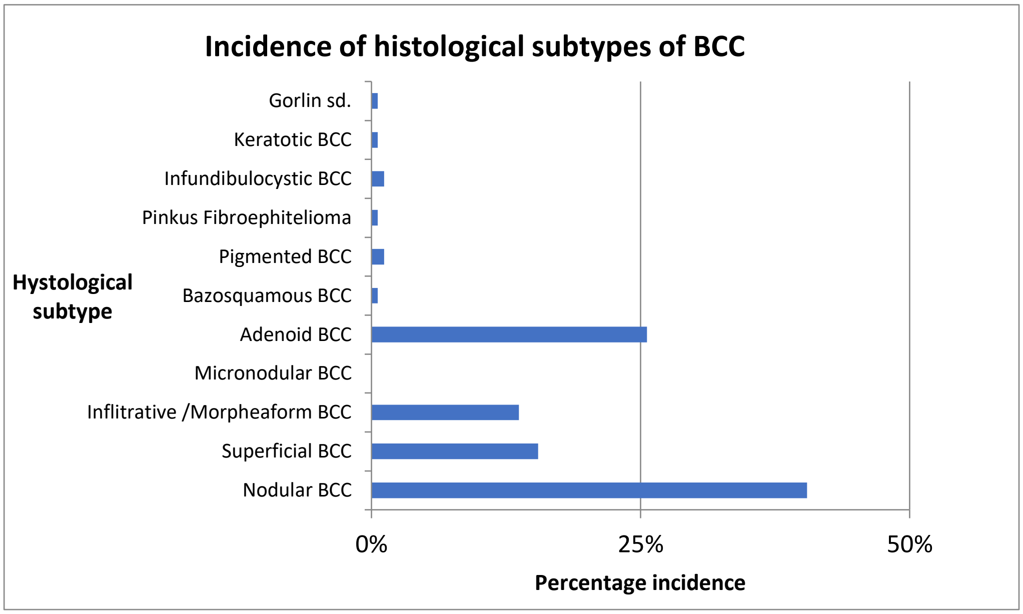
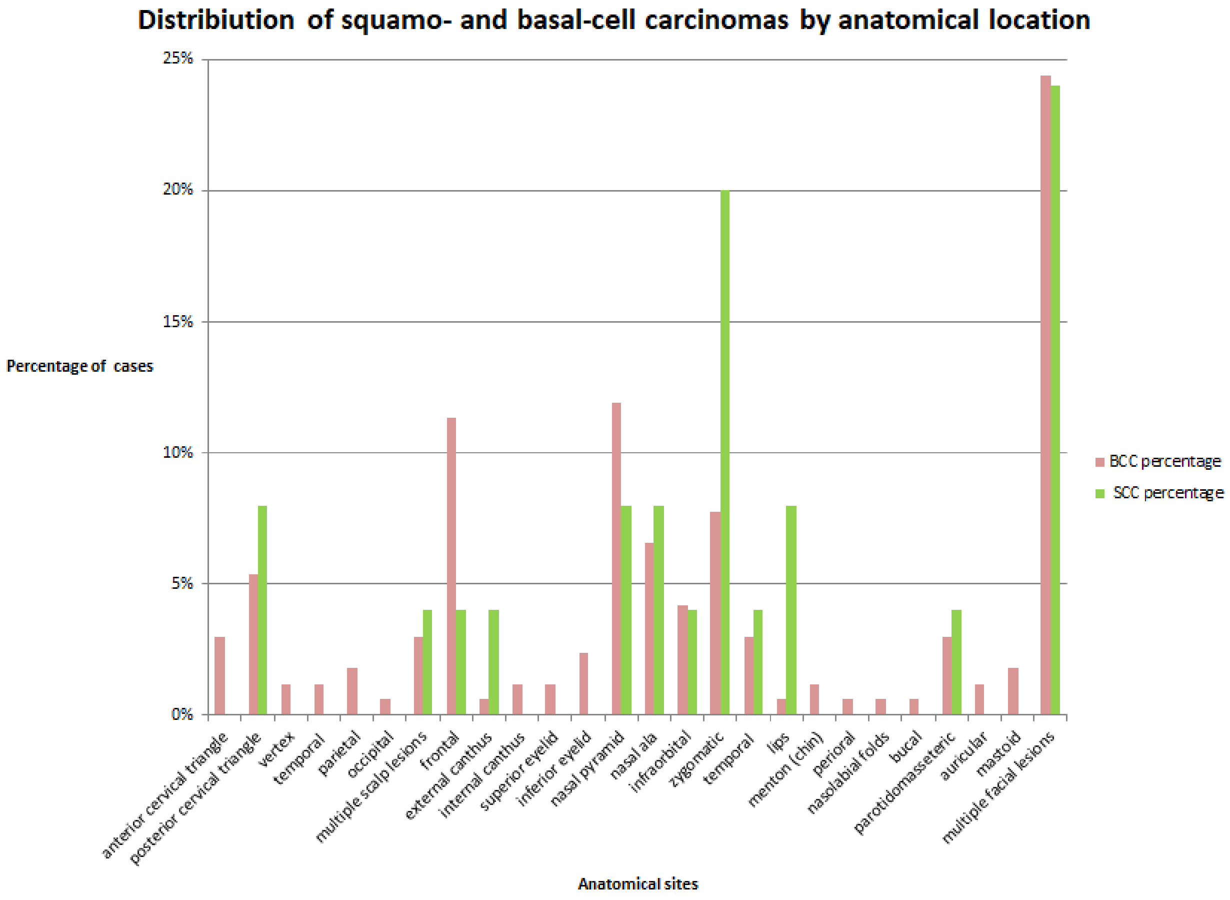


Based on the collected data, the majority of malignant lesions were located on the face (n = 152), a significantly higher number compared to those on the neck (n = 16) and scalp (n = 12). A more detailed anatomical breakdown of facial lesions revealed 20 cases on the forehead (10.3%), 23 on the nasal pyramid (11.8%), and 18 on the zygomatic region (9.2%). Additionally, 23 patients presented with multiple lesions on various facial subregions. Beyond the face, 24 other patients were identified with multiple malignant lesions distributed across the head and neck areas. Regarding the neck, the posterior cervical triangle showed a higher incidence (n = 11) compared to the anterior cervical triangle (n = 5). As for the scalp, lesion distribution was as follows: 2 cases on the vertex, 2 in the temporal region, 4 in the parietal region, 1 occipital lesion, and 3 patients with multiple scalp lesions.

When comparing the anatomical distribution of BCC and SCC, distinct patterns were observed. Several regions—including the anterior cervical triangle, vertex, temporal, , parietal, occipital, external canthus, upper and lower eyelids, chin (menton), perioral region, nasal area, auricle, and mastoid region—exhibited only BCC lesions, with no SCC cases recorded in these locations. On the forehead, 11% of all BCCs were located, compared to only 4% of SCCs, indicating a preferential distribution of BCC in this region. In contrast, the zygomatic region accounted for the highest proportion of SCC cases (20%), suggesting a predilection for SCC in this area. Within the posterior cervical triangle, SCC represented 8% of all cases found there, while BCC accounted for 5%, indicating a slightly higher occurrence of SCC in this particular region (Fig. 6).

The vertical dimension of malignant skin lesions showed notable variation across histological subtypes. Among basal cell carcinoma (BCC) types, the infiltrative/morphea form subtype had the highest mean depth (1.46 mm), followed closely by the superficial type (1.35 mm) and adenoid (solid adenoid) variant (1.30 mm). Less invasive subtypes such as nodular BCC had a mean depth of 1.21 mm, while rare variants like pigmented, Pinkus fibroepithelioma, and Gorlin syndrome-associated BCC displayed moderate vertical dimensions (ranging from 1.1 to 1.75 mm). Micronodular BCC was not reported in the dataset. In contrast, squamous cell carcinoma (SCC) subtypes tended to show greater vertical extension. Well-differentiated SCCs had the greatest average depth at 1.92 mm, while moderately differentiated SCCs averaged 0.97 mm, and poorly differentiated SCCs presented an intermediate value of 1.08 mm. These findings suggest a potential correlation between SCC grade and tumor depth.

Figure 6. Distribution of NMSC by anatomical location



Temporal analysis revealed fluctuations in lesion depth over the five-year period. For nodular BCC, the vertical dimension ranged from 1.0 mm to 1.49 mm, indicating no clear increasing or decreasing trend. A more pronounced variation was observed in the superficial BCC subtype, which reached a peak of 1.85 mm in 2022 and dropped to 1.06 mm in 2023 before rising again to 1.61 mm in 2024. Infiltrative BCCs peaked at 2.52 mm in 2022—suggesting a possible diagnostic delay or more aggressive presentation in that year. Regarding SCC, well-differentiated lesions consistently displayed greater depth than other SCC subtypes, with a maximum of 2.5 mm recorded in 2022. However, sample sizes for some years and subtypes are limited, warranting cautious interpretation.

A Mann–Whitney U test was performed to compare the vertical depth of BCC and SCC. The median depth in BCC subtypes was 2.20 mm, while SCC subtypes showed a median of 1.32 mm. The test yielded a U statistic of 129.5 and a p-value of 0.797, indicating no statistically significant difference between the two groups.

In order to assess whether there is a correlation between age and the vertical di-mension of the lesion, we applied Spearman's rank correlation test. The results (Spear-man's ρ = 0.023, p = 0.744) suggest that there is no significant association between the two variables, indicating that lesion thickness does not appear to vary meaningfully with patient age in our dataset.

A Mann–Whitney U test (which is non-parametric) was conducted to determine whether there was a difference in vertical dimension between males and females. The results indicated a statistically significant difference between the groups (U = 6473.0, p = 0.009), suggesting that sex may influence vertical dimension. The vertical dimension mean in men was 1.5 mm, while in female was 1.25 mm.

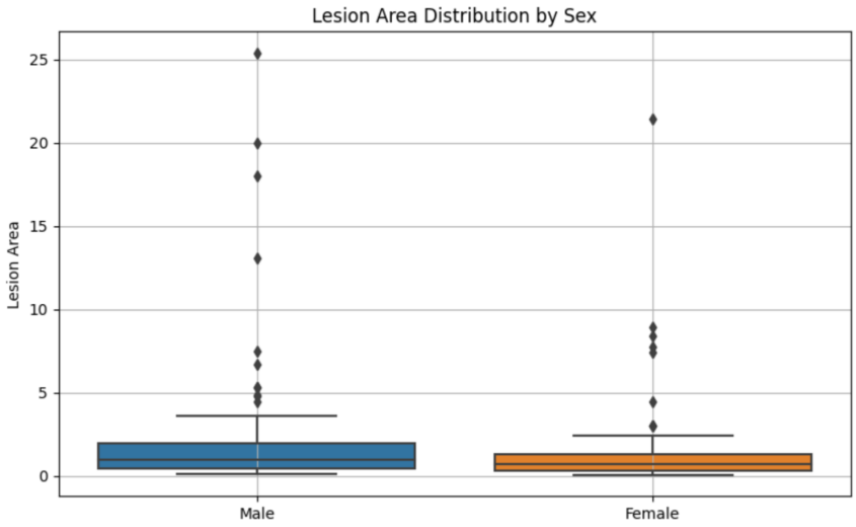
When analyzing the lesion surface area across basal cell carcinoma (BCC) subtypes, we observed considerable variability. The infiltrative/morpheiform subtype demonstrated the largest mean area, with an average of 2.47 mm², followed by the adenoid type (1.58 mm²) and nodular type (1.43 mm²). The superficial BCC subtype had a slightly higher average area (1.85 mm²) than nodular, which may reflect the lateral spread characteristic of this variant. Rare subtypes such as basosquamous/metatypical carcinoma presented a notably high mean area of 74.46 mm², although this finding is based on a single case and should be interpreted cautiously. Other rare variants, including keratotic, fibroepithelioma of Pinkus, and infundibular-cystic subtypes, exhibited relatively small areas ranging from 1.2 to 1.43 mm². The Gorlin syndrome-associated lesion had an average area of 1.55 mm².

For squamous cell carcinoma (SCC), the mean lesion areas were generally larger than most BCC subtypes. Well-differentiated SCCs demonstrated the highest average area, reaching 2.41 mm², while poorly differentiated tumors averaged 1.07 mm². Moderately differentiated SCCs had the smallest mean area among SCC subtypes at 0.77 mm².

A Mann–Whitney U test was also conducted to compare the lesion surface areas between BCC and SCC tumors. The analysis yielded a U statistic of 133.5 with a p-value of 0.60, indicating no statistically significant difference in lesion surface area between the two groups. This suggests that, despite observed differences in average lesion sizes, such as larger surface areas in some well-differentiated SCCs. These differences may be attributed to sample variability rather than a true underlying disparity in tumor size between BCC and SCC in this cohort.

There was a significant difference in lesion area between males and females (U = 6290.0, p = 0.0095) (Fig. 7). While the median lesion area was higher in males (1.0 cm² vs. 0.7 cm²), a rank-based comparison showed a small-to-moderate effect (rank-biserial r = −0.21), likely influenced by high outliers in the female group. A lesion measuring 74.46 mm in a female case was excluded from the analysis to minimize the impact of outliers and ensure that the results more accurately reflect the central tendency and variability within the dataset.

Figure 7. Grouped bar chart showing lesion area distribution by sex



DISCUSSION

Comparing the data we collected with other clinical studies conducted in recent years in different regions of Romania, a consistent national trend in the incidence of non-melanoma skin cancers can be observed. Both a one-year 2022 study from South-Western part of the country (Craiova city) and a five-years 2014 study from the North-Eastern region (Iasi city) support and validates our findings, confirming their reliability and broader applicability. Thus, both studies indicate a prominence of basal cell carcinomas among the identified NMSC cases, with reported proportions of 55% in the 2014 study and 75,5% in the 2022 study [18,19]. Notably, the 75,5% figure closely aligns with our own findings, where BCC accounted for 86% of cases [18]. This may reflect either an increasing trend in the incidence of BCC over time, or differences in exposure to specific risk factors depending on region. Other similarities to our study include the predominance of the nodular subtype of BCC, which was the most frequently encountered variant in both comparative studies [18,19]. In our study, nodular BCC accounted for 40% of cases, closely matching the 40,4% reported in Iasi [19]. Additionally, all three studies identified the face as the most common anatomical site for tumor occurrence, which may support the correlation between UV exposure and lesion development [18,19]. Moreover, a slight female predominance was observed consistently: women represented 52% of cases in our study and 53% in the Craiova one [18]. These very similar findings highlight the potential role of common environmental and behavioral risk factors and support the need for continued epidemiological monitoring in Romania.

The observed seasonal variation, with higher incidence on non-melanoma skin cancers during autumn and lower numbers in spring, is consistent with the findings of previous studies. A 2017 study from North Carolina concluded that the diagnosis rates of BCC and SCC were highest in October and August, so at the end of the festival season, that confirmed the idea of delayed diagnosis after summer UV exposure [20]. According to Bianconi et al., the Umbria region of Italy had also a higher incidence of NMSC during autumn (mostly October), which was explained as a late cancer progression effect of UV exposure [21]. These similarities support the hypothesis that medical consultation is often delayed due to the clinical appearance of suspicious skin lesions following prolonged summer sun exposure. Consequently, many lesions are diagnosed in the following season- autumn- after cumulative sun damage becomes clinically. Given the seasonal pattern of delayed diagnosis, it is crucial to examine potential preventive measures, such as public health campaigns targeting periods of high UV exposure months. These interventions should aim to raise awareness about the risks of sun damage, promote early skin examinations, and encourage timely medical consultations.

The lack of statistical significance regarding the vertical dimension and area may be due to sample size limitations or uneven subtype representation within groups. For example, rare or extreme outliers like the metatypical BCC area (74 mm²) can skew averages and impact variability. Future studies with larger, more balanced samples may provide clearer insight into surface area differences between malignant skin lesion subtypes.

The recent Covid-19 pandemic impacted in a negative way the worldwide healthcare systems, leading to disruptions in routine medical services. As observed in Table I, there were no admissions of dermatology cases in our department between April 2020 and June 2021, which indicates that dermatological services were not operational through this period. There are several existing factors which contributed to the activity disruption. Firstly, the pandemic's health care focus likely caused resource redirection. Secondly, institutional policies mandating restriction consults of any case that is not an emergency severely capped support for patients. Another reason may be the fact that considerable sections of the medically unwell population opted not to attend medical facilities due to the high likelihood of contracting the virus, which adds even more weigh. This local experience aligns with global trends observed during the pandemic. A study analyzing data from the American Academy of Dermatology's DataDerm registry reported a significant decrease in in-person dermatology visits between April 2020 and June 2021, with a corresponding increase in tele-dermatology appointments [22]. However, expanding tele-dermatology services did not ascertain timely diagnosis and prompt treatment for a significant number of patients. Research shows lockdowns led to a diverse range of disruptions that caused cancer diagnoses to be missed on a global scale. The World Health Organization's International Agency for Research on Cancer estimated that about one million cases of cancer went undetected globally during the lockdown because of Covid-19 [23]. This statement emphasizes the need for strategies to maintain essential healthcare services even during public health crises. The increasing number of diagnoses of cutaneous cancer in the post-pandemic period, could stem from the backlog of cases that went undiagnosed when routine dermatological checkups were either postponed or unavailable.

In the present study, a statistically significant difference was observed in the vertical thickness of non-melanoma skin cancers (NMSC) between male and female patients, with mean measurements of 1.5 mm and 1.25 mm, respectively. This disparity, though numerically modest, holds substantial clinical relevance, as increased tumor thickness is associated with a higher risk of local invasion and recurrence.

Several factors may contribute to this gender-based difference in tumor presenta-tion. One of them could be considered the delayed medical consultation among men. Men are generally less likely to engage in preventive healthcare practices. According to a 2009 study, the white middle-class men were the most affected by melanoma because of the delay in seeking medical attention for skin lesions [24]. This tendency may result in the progression of tumors to greater thickness before diagnosis. Another contributing factor to the gender difference seems to be the sun protection behaviors. The American Association for Cancer Research reported in a 6 years study, that women are more likely to adopt behavioral changes as using sun protection measures like including sunscreen and protective clothing, to prevent future cutaneous cancers [25]. They would also limit more the outdoor activity and when outside, they would seek shade more than men [25]. This may contribute to earlier detection and thinner tumors at diagnosis.

Although our study shows a higher incidence of NMSC in urban areas, this finding is most likely explained by the location of the study center- a tertiary hospital in Bucharest. The majority of patients included in the study were residents of Bucharest, which leads to an overrepresentation of urban cases. This does not necessarily reflect a higher exposure to risk factors in urban settings, but rather the geographic bias introduced by easier access to specialized dermatological care in the capital. As shown in a retrospective U.S. study with patients recruited from two primary care practices in one rural Maine regional health system, rural patients often face significant barriers to dermatological evaluation and treatment [26]. That may include longer travel distances, limited availability of specialists and socioeconomic constraints.

Another point to discuss is the predominance of basal cell carcinoma in our studied population, with a higher incidence of the nodular subtype (40% of the BCC cases). These findings are aligning with the worldwide trend, as the BCC is well-known the most frequent skin cancer in adult patients with fair skin, the nodular lesions accounting for more than 60% of all BCCs [27]. Nodular subtype are usually slow growing, non-aggressive tumors, belonging to the indolent-growth subset [10]. Thus, its predominance in the studied population may indicate that most cutaneous neoplasms in fair-skin adults are having a favorable outlook. This may be explained by the commonly less aggressive nature of the nodular variant, or by the fact that they are being detected in an early stage, before becoming invasive. The last one is not a well-supported hypothesis, as we have to emphasize the frequent delay in making a definitive diagnostic due to several contributing factors like the still existing need for access to a good dermatological care for all socioeconomic groups.

Regarding squamous cell carcinoma, our study revealed a greater average vertical dimension of well-differentiated lesions (1,92mm), compared to all the mean depths of the different subtypes of BCCs. The bigger vertical growth of SCC can have potential implications in the tumor outcome, as may be an indicator for the cancer aggressiveness. According to a 2024 literature review, the cutaneous squamous cell carcinoma of the head and neck can present metastasis in approximative 2,5% of patients, most often localized in the level II lymph nodes and the parotid glands [28,29]. Unlike BCC, cSCC can spread both nearby and distant locations, one of the high-risk criteria for the metastasis being represented by a depth invasion greater than 6 mm [28,29]. Although none of the studied lesions were deeper than 6 mm, it is necessary to highlight the importance of correlating depth patterns of cSCCs with their metastatic rates and with the right choice of treatment. The primary method of treatment remains the surgical resection, but the tumor depth and size can dictate the type of therapy need to be used. The vertical dimension of cSCCs influences also the follow-up protocols, as patients with greater tumor depths (so high-risk groups) requires a tighter follow-up [29].

Lastly, although most NMSC cases are treated successfully with local excision, ad-vanced or recurrent head and neck lesions (particularly large or deep infiltrating squamous cell carcinomas) may require complex surgical resections. In such cases, reconstruction becomes critical not only for functional and aesthetic restoration but also for maintaining the patient’s quality of life. Free flaps and other advanced reconstructive techniques, such as the radial forearm or anterolateral thigh flap, offer valuable options. The success of these procedures underscores the importance of surgical expertise and a multidisciplinary approach, as emphasized in recent scoping reviews. [30]

Our study's possible limitations should be taken into account when interpreting the results as they may have introduced bias. Since only 180 patients were chosen from a single tertiary medical center, the study had a relatively small sample size and was carried out over a five-year period. Since it ignores possible variations in clinical, histo-pathological, or demographic characteristics among various populations or geographical areas, this may lower its statistical power and have an impact on the findings' generalizability. Furthermore, the COVID-19 pandemic coincided with a portion of the study, which disrupted data collection and resulted in fewer patients having access to medical services. Clinical activity was interrupted by these contextual factors, resulting in missing or insufficient data. Notwithstanding these drawbacks, our research still provides insightful information.

Nevertheless, we emphasize the very actual need of further prospective studies which should assess the targeted screening programs influence in early cancer detection and diagnosis, and the effectiveness of different treatment strategies in patients with head and neck non-melanoma skin cancers.

CONCLUSIONS

The study identified a progressive increase in the incidence of malignant skin lesions from 2020 to 2023, followed by a decrease in 2024. This trend could be attributed to factors such as the impact of the COVID-19 pandemic on healthcare access and a possible post-pandemic surge in cases. Continued monitoring is essential to validate whether this trend persists in subsequent years.

The analysis revealed a statistically significant variation in skin cancer diagnoses across seasons, with the lowest incidence observed in spring and relatively similar fre-quencies in summer, autumn, and winter.

The face was the most common location for malignant lesions, emphasizing the significant role of sun exposure in the etiology of NMSC. BCC was the most frequent histological subtype, with nodular BCC being particularly prevalent. In contrast, SCC, although less common, demonstrated greater metastatic potential and depth, especially the well-differentiated subtype.

Our analysis revealed statistically significant differences in lesion size between sexes, with both area and vertical dimensions being greater in males compared to fe-males.

The majority of NMSC cases were recorded in urban areas, particularly Bucharest, suggesting a potential link between urban living and higher skin cancer incidence or, conversely, a lack of adequate healthcare access in rural regions. Additionally, while the sex distribution was relatively balanced, males exhibited significantly greater lesion depths compared to females.

Abstract: Background Medical rescue transfer and handover in manned spaceflight is a critical component of space rescue operations, directly impacting the safety and well-being of astronauts. Objective This study aims to develop a comprehensive checklist for the medical rescue transfer and handover processes associated with manned spaceflight, thereby enhancing the efficiency of these procedures. Methods The checklist was designed and implemented during practical training sessions focused on manned space medical rescue. Participants were divided into two groups: one utilizing the checklist for transfer handover and another relying on verbal communication. Key metrics such as transfer time, quality of handover, and satisfaction scores were collected and analyzed for both groups. Results The group employing the checklist demonstrated significantly improved outcomes compared to the verbal group in terms of transfer time, quality of handover, and overall satisfaction scores (P < 0.001). Conclusion The implementation of checklist management has been shown to enhance both the efficiency and quality of transportation and handover processes, establishing a robust foundation for successfully executing manned space medical rescue missions.

Keywords: Manned Space Medical Rescue; Transfer; Handover; Checklist Management

INTRODUCTION

China's manned space program has advanced to the stage of conducting missions involving a space station, resulting in significantly extended durations for astronauts' stays. These missions are increasingly arduous and complex, which elevates the likelihood of accidental injuries and illnesses [1,2,3]. Space medical rescue is a critical component in ensuring astronaut safety and constitutes an essential aspect of manned space system engineering [4,5]. The efficiency and quality of transfer and handover during medical rescue directly impact the stability and prognosis of astronauts. Research indicates that standardized transfer handovers can reduce handover time, enhance accuracy and efficiency, and decrease the occurrence of adverse events. Checklist management has emerged as an effective strategy to mitigate errors arising from oversight; it offers advantages such as rapid comprehension, straightforward implementation, and precise handovers [6,7]. Currently, checklist management has been successfully employed in emergency evacuation and transfer protocols by foreign Marine Corps units, yielding positive outcomes in reducing adverse incidents while improving the quality of transfers and handovers [8].

This study aims to implement checklist management within nursing transfer processes during aerospace medical rescue training. A statistical analysis will be conducted on the time taken for these transfers, the quality achieved therein, as well as satisfaction levels among nursing staff compared with traditional oral handovers. This approach seeks to provide insights into methodologies for enhancing both the quality and efficiency of aerospace medical rescue operations alongside nursing transfers and handovers.

One population that has been identified as vulnerable to acquiring HIV infection is military personnel, due to frequently reported high-risk sexual behaviour [9,10] or to their high mobility and exposure to biologically foreign environments [11,12].

MATERIALS AND METHODS

1. Design of transfer handover list

By convening a panel of eight experienced experts in the field of space medicine, we developed a comprehensive checklist for manned space rescue, transfer, and handover procedures. In designing the content, we prioritized the timeliness of first aid interventions prior to astronauts exiting their cabin. This checklist encompasses critical information including the arrival time of medical rescue personnel, the timing of astronaut cabin egress, on-site emergency treatment duration, astronaut evacuation timing, as well as vital signs monitoring and condition changes throughout the evacuation process [8]. As illustrated in Table 1, the handover list is categorized into four dimensions comprising fifteen items:

(1) Basic Information: This section includes data such as astronaut identification number, gender, age, exit time from the cabin, and entry time into the medical transport vehicle.

(2) Preparation Before Transport: This dimension covers essential vital signs of astronauts prior to transport along with safety measures for astronauts themselves; it also addresses preparations by medical staff and necessary equipment.

(3) Observation During Transport: Key observations during transportation include monitoring astronauts' vital signs—such as consciousness level, blood pressure readings, heart rate fluctuations, oxygen saturation levels—and noting any sudden changes in their condition.

(4) Transfer and Handover: The final category consists of data regarding consciousness levels and vital signs at transfer points; skin status assessments; past medical history including allergies; venous access details; artificial airway management; and medications administered during transit.

The signature section was duly signed off by both nursing staff involved in pre-cabin treatment and transport as well as receiving nursing personnel at the destination hospital. Additionally, precise records were maintained detailing each step of an astronaut's transfer to a ward down to minute-level accuracy. The transfer handover documentation exists in duplicate copies that are stored separately to serve as formal handover references.

2. Training of transfer handover list

After the completion of the design for the transfer and handover checklist, nursing staff training was conducted by the organizers in accordance with expert consensus on astronaut treatment before the re-entry module of the landing site of space station mission[4]. This training also adhered to the Standard Operating Procedure (SOP) for emergency medical care for astronauts[9,10,11], as well as operational specifications pertaining to medical care and support during space station missions[12,13]. Methods such as group discussions and scenario simulation demonstrations were employed to elucidate each item on the checklist systematically. The effectiveness of this training was assessed through on-site questioning, ensuring that participants comprehensively understood each item and minimizing potential errors in documentation.

3. Group study on the transfer handover list

To implement the transfer and handover checklist in manned space medical rescue training, a study was conducted with two groups: a control group utilizing traditional oral handover methods and an experimental group employing the checklist handover approach. Each group consisted of 15 participants. The metrics evaluated included transfer preparation time, transfer handover time, and total transfer time.

Transfer preparation time refers to the duration required for the simulated astronaut to enter the transport carrier, during which the medical team counts personnel, consumables, and equipment while confirming both the condition of the injured individual and the status of all equipment. Transfer and handover time encompasses the period needed for the simulated astronaut to exit from the transport carrier and be transported to the astronaut ward. This phase includes transferring essential information such as basic details, vital signs, level of consciousness, and any changes in condition between pre-cabin rescue nursing staff and posterior support hospital nursing staff.Total transit time is defined as the cumulative sum of both transit preparation time and transit handover time.

4.Evaluation

The handover process with the posterior branch hospital was systematically evaluated by the training team leader during each transfer. The quality of handover for both the experimental group and the control group was assessed based on three key components: preparation prior to transfer, the actual transfer and handover process, and comprehension of the patient's disease status. Each component was assigned a score ranging from 1 to 3 points, where 3 points indicated excellent performance, 2 points denoted good performance, and 1 point represented fair performance.

Concurrently, a satisfaction questionnaire was distributed to nursing staff at the backward branch hospital to gauge their satisfaction regarding the transfer and handover process across six dimensions: vital signs monitoring, level of consciousness, changes in condition, venous access management along with other pipelines, medication administration, and skin conditions. Each aspect received a score between 1 (minimum) and 10 (maximum).

5.Statistical analysis

All data were analyzed using IBM SPSS Statistics 24 . Measurement data that conformed to a normal distribution were presented as mean(M) ± standard(SD) deviation. Count data were expressed in terms of frequency (percentage). The comparison of normally distributed measurement data between the two groups was conducted using an independent samples t-test.

RESULTS

1. Transit time

The transfer time was significantly reduced in the experimental group compared to the control group. In the experimental group, the transfer preparation time averaged 13.27±1.10 minutes, while the transfer handover time was 9.73±1.67 minutes, resulting in a total transfer time of 23.00±1.89 minutes. Conversely, in the control group, the average transfer preparation time was 18.13±2.07 minutes and the transfer handover time was 14.80±1.97 minutes, leading to a total transport time of 32.93±2.84 minutes. The difference between these two groups was statistically significant (P <0.001). Detailed results are presented in Table 2.

Table 2: Comparison of transit times in different groups

Groups	Number	Transit Preparation Time (min)	Transfer Handover Time (min)	Total Transit Time (min)
Control group	15	18.13±2.07	14.80±1.97	32.93±2.84
Experimental group	15	13.27±1.10	9.73±1.67	23.00±1.89
T		10.21	13.65	15.1
P		<0.001	<0.001	<0.001

2. Quality of transfer handover

The scores of the experimental group surpassed those of the control group across three dimensions: preparation prior to transfer, the transfer and handover process, and mastery of disease status. As illustrated in Table 3, the mean scores for preparation before transfer, transfer handover process, and mastery of disease status in the experimental group were 3.00±0.00, 2.53±0.51, and 2.60±0.50, respectively. In contrast, the corresponding scores for the control group were 2.40±0.13, 1.67±0.49, and 1.60±0.63. The differences between these two groups were statistically significant (P < 0.001).

Table 3: The quality of transfer handover was compared in different groups

Groups	Number	Prepare Before Transfer	Transfer Handover Process	Mastery of Disease Status
Control group	15	2.40±0.13	1.67±0.49	1.60±0.63
Experimental group	15	3.00±0.00	2.53±0.51	2.60±0.50
T		-4.58	-6.5	-5.12
P		<0.001	<0.001	<0.001

3.Satisfaction

Table 4 presents the satisfaction survey scores of medical staff at the posterior branch hospital. The satisfaction scores for the experimental group regarding vital signs, state of consciousness, condition changes, venous access and various pipelines, medication, and skin conditions are as follows: 9.83 ± 0.27, 9.41 ± 0.37, 9.56 ± 0.38, 9.41 ± 0.37, 9.66 ± 0.38, and 9.67 ± 0.38 respectively. In contrast, the control group's satisfaction scores in these same categories were: vital signs (8.73 ± 0.45), state of consciousness (8.57 ± 0.39), disease changes (8.75), venous access and each pipeline (8.63 ± 0.46), medication (8.79 ± 0 .41), and skin conditions (8 .59± 0 .50). The results indicate that the experimental group exhibited significantly higher satisfaction levels compared to the control group (P < 0 .001).

Table4: Comparison of disability among soldiers with different reasons

Groups	Number	Vital Signs	State of Consciousness	Changes in Condition	Pipe Line	Medication	Skin
Control group	15	8.73±0.45	8.57±0.39	8.75±0.41	8.63±0.46	8.79±0.29	8.59±0.50
Experimental group	15	9.83±0.27	9.41±0.37	9.56±0.38	9.41±0.37	9.66±0.38	9.67±0.38
T		-9.39	-8.82	-8.84	-6.24	-8.56	-7.63
P		<0.01	<0.01	<0.01	<0.01	<0.01	<0.01

DISCUSSION

To ensure the life and health of astronauts is fundamental to manned space projects. A review of the history of manned space flight worldwide reveals a number of accidents that have resulted in significant losses. In the United States, there have been 19 incidents and failures during manned space flights, leading to 18 fatalities. The former Soviet Union conducted numerous manned space missions, which also resulted in injuries among astronauts, including six deaths [14,15]. To date, all of China's manned space missions have been successfully completed without any serious injuries. As our country embarks on a new phase with its space station program, the frequency of manned launch missions is increasing, while records for in-orbit flight durations continue to be extended. This rise introduces unforeseen factors and maintains an ongoing risk of accidental injury to astronauts. In the event of such an accident, medical rescue serves as the final safeguard for astronaut safety.

The transfer and handover process is a critical component of aerospace medical rescue, significantly influencing the prognosis of injured individuals and patients. The occurrence of adverse events during transfer and handover is closely associated with various factors, including equipment issues, patient conditions, communication barriers, and other challenges faced by medical personnel [16,17]. Implementing an appropriate transfer and handover checklist can enhance communication efficiency among medical staff, enabling them to quickly and effectively comprehend the patient's condition while minimizing the risk of overlooking essential information. This ultimately ensures the safety of patients during their transfer [18,19].

By utilizing a standardized checklist for transfer handovers that delineates key points and critical content in written form, a unified standard is established. This approach improves both the accuracy and efficiency of the transfer process while preventing omissions of vital items. Consequently, it facilitates evidence-based practices in transfer handovers and safeguards patient safety throughout this procedure [20]. Research indicates that employing a checklist for handovers can reduce the incidence of adverse events during transfers from 13.8% to 5.4%, thereby significantly enhancing both quality and efficiency in these processes [21].

Checklist management was implemented in the transfer and handover process of aerospace medical rescue training. Utilizing a transfer and handover checklist, each item was marked off systematically, resulting in a rapid and concise documentation process with accurate and clear recorded content. The critical links that are often overlooked during handovers were consolidated into a standardized format to mitigate the risks associated with oral communication, thereby reducing the likelihood of omissions or repetitions. This approach not only saves time during transfers but also ensures that medical personnel at receiving hospitals have comprehensive access to vital signs and overall injury assessments of simulated casualties throughout the entire evacuation process [22]. The findings from this study indicated that the checklist-based handover group (experimental group) outperformed the oral handover group (control group) significantly across two evaluation metrics: transfer handover time and quality. Furthermore, medical staff at the receiving hospital expressed markedly higher satisfaction regarding six key aspects of the transfer process compared to their counterparts in the oral handover group (control group).

The practice of aerospace medical rescue training has demonstrated that checklist management offers several advantages:

(1) Ensuring the accuracy of transfer and handover information. Traditional oral handovers often suffer from inaccuracies in information transmission, ambiguity regarding key content, omissions of critical disease data, and sometimes deficiencies in the objectivity, accuracy, and completeness of the conveyed information. These unclear handovers and existing shortcomings directly impact the quality of care following transfer. By utilizing a tabular format, a nursing transfer and handover checklist can effectively reflect the basic situation and condition of simulated astronauts in a simple, comprehensive, and intuitive manner. This checklist provides complete information—including vital signs, illness details, rescue efforts, and nursing considerations—for medical personnel at posterior support hospitals. It serves as both a reference point for handover tasks and contributes to making the process more standardized and evidence-based.

(2) Improving the quality and efficiency of transfers and handovers. The checklist facilitates an item-by-item review according to its contents during handover sessions; this approach significantly reduces omissions related to key content or data due to limitations in energy levels or memory capacity among medical staff—factors exacerbated by misunderstandings or time constraints. Consequently, it shortens overall handover duration while substantially enhancing its quality. Research findings indicate that groups utilizing checklists for handovers performed significantly better than those relying on oral communication concerning both transfer times and overall quality of transfers. Following implementation of checklist-based procedures for handing over responsibilities, there is clear evidence that both efficiency and quality are markedly improved while ensuring safety and timeliness throughout the process.

(3) To ensure the safety of astronaut transportation, space medical rescue is critical to both the life and safety of astronauts as well as the overall success or failure of the mission. In the event that an astronaut sustains an accidental injury, there are heightened risks associated with the transfer process. The implementation of a checklist handover serves as a safe nursing practice designed to facilitate effective communication before, during, and after the transfer based on a predetermined transfer handover list [23]. The self-designed transfer handover checklist plays a vital role in conducting risk assessments prior to transfer, thoroughly evaluating timing considerations, and emphasizing careful monitoring of conditions along with emergency interventions throughout the transfer process. Upon safely reaching their destination for transfer, this checklist is utilized once more to convey essential information

regarding vital signs, consciousness levels, venous access status, various drainage tubes in place, medication administered, and any changes in condition experienced by the astronauts. This systematic approach proves beneficial for medical personnel at receiving facilities by enabling them to swiftly assess conditions and execute necessary procedures effectively.

CONCLUSION

With the successful completion of the inaugural in-orbit rotation involving the astronaut teams of Shenzhou 14 and Shenzhou 15, China's space station has transitioned into a long-term operational mode. Consequently, space medical rescue and support missions will now be conducted under standard working conditions. This study demonstrates that effective checklist management can enhance both the efficiency and quality of the transfer handover process. The objective of this approach is to normalize, standardize, and systematize the procedures for space medical rescue transfers and handovers, thereby establishing a robust foundation for the successful execution of astronaut medical support and rescue operations.

Conflicts of interest and sources of funding

The authors declare no conflict of interest and this research received no external funding.

Authors' contribution

The initial draft was prepared and revised by JL, while GH, PS, XG, and LD contributed to the collection of information and the preparation of the dataset. YW further refined the analyses and provided essential support for the manuscript. LS and YT supervised all aspects of the study, including the design of the data analysis plan, oversight of the data analysis process, validation of results, and writing of the manuscript based on the first draft. All authors participated in reviewing and finalizing the manuscript; furthermore, all interested parties have read and approved it.

Ethics approval and consent to participate

This study does not consider pertinent ethical issues related to individuals.

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at office@rjmm.ro.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers may cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor may not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Academic Editor. The Editor-in-Chief reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at: http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

– Accessible to the public at no charge;

– Searchable by standard, electronic (Internet-based) methods;

– Open to all prospective registrants free of charge or at minimal cost;

– Validates registered information;

– Identifies trials with a unique number; and

– Includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, a target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal, you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The Journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 200 words. Abstracts for original articles should be formatted as detailed in the word form. Titles must not be longer than 120 characters (including spaces). In every article, there must be three to ten pertinent keywords specific to the article yet reasonably common within the subject discipline.

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article. This should be cited as Rom. J. Mil. Med. (year); (vol): [issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “miniseries” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this

avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-analyses and Systematic Reviews are suggested to be limited to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are suggested to be limited to 3000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Executive Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In Part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate.

Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling

The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units

All measurements must be given in SI units as outlined in the latest edition of Units, Symbols, and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations

Abbreviations should be used sparingly and only where they ease the reader's task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: the title page; and the main text file according to the word model.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or an article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented according to the word model. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 200 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. If appropriate, divide the abstract with the headings: Background and Aim, Methods, Results, and Conclusions. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to ten keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser – http://www.nlm.nih.gov/mesh/meshhhome.html.

Text

Authors should use the word form in editing the submitted material.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square parentheses in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

Use Index Medicus as the style guide for references and other journal abbreviations.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table and legend must be

understandable without reference to the text. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, •, ‣ should be used (in that order) and *, **, *** should be reserved for P-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication:

Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at office@rjmm.ro. A cover letter containing an authorship statement should be included. The cover letter should include a statement covering each of the following areas:

– Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author. It is not accepted the idea of equal contribution.

– Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

– A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

– For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement about any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

– For clinical trials, these have been registered in a publicly accessible database (see more under 'ETHICAL CONSIDERATIONS (Further Information)' later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review. Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using the word model that is to be found on the web page (http://revistamedicinamilitara.ro/wpcontent/uploads/2022/07/Macheta-articole.docx).

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, high-resolution figures (at least 300 d.p.i.) saved as .eps, .jpg or .tif files are required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted Articles

Accepted Articles are published online after final acceptance, and appear in PDF format only.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing the proof of acceptance. It is therefore essential that a working e-mail address is provided for the corresponding author.

Obesity and osteoporotic fractures

Florica Şandru[1,2], Mihai C. Dumitraşcu[2,3], Simona E. Albu[2,3], Mara Carsote[2,4], Ana Valea[5,6]

Abstract: *Obesity correlates with a higher risk of fractures in some sites as vertebras, upper arm, and legs. This is a narrative mini-review focused on several key points that link obesity with osteoporosis. Waist circumference may a better predictor of fractures than body mass index (BMI) in obese females. Even obese menopausal women have an extra source of estrogens in fat tissue this actually is not enough to offer a complete protection against osteoporotic fractures. Low levels of testosterone in males induce a higher risk of fall dependent or independent of sarcopenia (which is more evident in elderly). High BMI is correlated with vitamin D deficiency. Obesity is a contributor to muscle damage and decline due to fat accumulation and inefficient fuel utilisation by the muscle, namely sarcopenic obesity, regardless the age. Associated type 2 diabetes mellitus involves bone damage and fracture risk due to glycated proteins of the matrix, the changes of adipokines, increased cortical porosity, high risk of fall because of blood pressure and glycaemia anomalies, visual disturbances, renal and peripheral nerves diabetes-associated conditions etc. The fracture risk is also augmented via fat derived cytokines and chronic inflammation. Even it seems logical that the weight correction though bariatric surgery reduces the fracture risk in obesity, actually data from longitudinal studies pointed that, despite the procedure is life saving, it does not actually protect against osteoporosis which is regarded as a potential long-term complication. A high fracture burden in obesity should increase the level of awareness for practitioners of different medical areas due to multiple levels of complications and to the epidemiological impact of obesity.*

Keywords: *obesity, osteoporosis, fracture*

INTRODUCTION

Obesity currently represents a pandemic issue and every medical and surgical speciality includes different complications of obesity from cardiovascular conditions, type 2 diabetes mellitus and insulin-resistance, some types of cancer to infections at any level including skin, lungs, urinary tract, gastrointestinal infections, respective infertility, sleep apnoea, non-alcoholic fatty liver disease, depression, and finally any of these or their combination may increase the overall mortality. [1, 2, 3, 4] The increasing epidemiological impact has brought a large area of concern worldwide. [1, 2, 3, 4] The endocrine frame of obesity perception is related to hypothyroidism, hypercortisolemia, male hypogonadism, female hyperandrogenemia, and lately to osteoporosis and fragility fractures, including hypovitaminois D. [5] A systematic review associated with a meta-analysis published in 2019 by van Hulsteijn et al. included 68 studies (meaning 19,996 obese subjects). [6] The study identified that 28% of the individuals had reduced thyroid function of different severities, while 0.9% of them had hypercortisolemia. [6] When it comes to males the prevalence of hypogonadism was between 32 and 42%

depending on criteria. [6] Contrary to historical records that consider obese women protected against osteoporosis because of the estrogens excess at the level of adipose tissue, last two decades brought enough proves that actually this hypothesis is not entirely true. [7]

AIM

Our purpose is to introduce data related to the risk and prevalence of osteoporotic fractures in obese persons.

MATERIAL AND METHOD

This is a narrative mini-review of the literature based on a research focused on several practical key points that correlate obesity with osteoporosis. A number of 69 articles have been included in the selection.

RESULTS – GENERAL DATA

The influence of abdominal obesity versus body mass index

The link between obesity and fractures may be expressed as BMI (Body Mass Index), either as abdominal obesity. A cross-sectional study published in 2019 showed that among 669 elderly women 65 had fragility fractures of different sites, with an average age of 73.9 years. [8] BMI was not associated with fragility fractures but abdominal obesity suggested by a waist of more than 88 centimetres (cm) was, regardless the presence of different clinical risk factors as smoking or age etc. [8] Some authors suggested that actually the waist circumference is a better predictor of fractures than BMI in overweighed and obese females. [8,9] It seems that low body mass index as well as high content of body fat, respective increase BMI both are associated with high fracture risk, especially at vertebral site. [9] Generally the fat content of the body has been reported as an accurate predictor factor for several conditions including cardiovascular and metabolic morbidities. [10] On the other hand, the influence of BMI on osteoporotic fractures risk may include the fact that low and high BMIs are considered at risk for fractures despite Bone Mineral Density (BMD) values which are directly correlated with BMI and it might not reflect the real fracture risk in obese individuals. [11, 12]

Postmenopausal women

The female individuals in menopause suffer of estrogens deficiency related to menopause thus causing bone loss and low trauma fractures. [13, 14, 15] Even obese menopausal women have a second source of estrogens in fat tissue which is superior to normal weighted subjects this actually is not enough to offer a complete protection against osteoporotic fractures. [13, 14, 15] Some studies pointed a similar rate of fractures in menopausal women regardless they were obese or not and others showed a different distribution depending on site, for instance: a high risk is for vertebral fractures, humerus, upper arm, leg and ankle while a low risk has been described for hip and wrist. [13,14,15] This aspects are most probably related to the physics of fall depending on weight. [13, 14, 15]

Male hypogonadism

Even osteoporosis is less frequent in males, the prevalent fractures are found in obese men through associated hypogonadism independent of the BMI values. [16, 17, 18] Low levels of testosterone induce a higher risk of fall dependent or independent of sarcopenia (which is more evident in elderly). [16, 17, 18] Testosterone therapy may reduce the fracture risk. [16, 17, 18]

Hypercortisolemia

Glucocorticoid osteoporosis is a well known cause of obesity-related type of secondary osteoporosis. [19, 20, 21] The obese subjects without Cushing’s syndrome display chronic high values of basal cortisol which seems suppressible at dexamethasone inhibition test. [19,20,21] Chronic autonomous secretion of cortisol is identified in patients with adrenal incidentaloma with an age-dependent incidence and this has been reported to increase the risk of osteoporosis independent of age. [22, 23, 24]

Hypovitaminosis D

The interest in the area of hypovitaminosis D has been explosive during the last decades. A higher BMI is positively correlated with a high risk of vitamin D deficiency based on large epidemiological studies. [25, 26, 27[However, there is still a matter of debate regarding which is the cause and which is the effect. [28, 29, 30] The potential causes of vitamin D lack include: the relative immobility and decreased sun exposure, lower dietary intake, decreased intestinal absorption, high accumulation of vitamin D at the level of adipose tissue since it is a liposoluble vitamin thus a lower bioavailability of the vitamin D. [31, 32, 33] Decreased levels of 25-hydroxivitamin D are contributors to impair muscle resistance and to sarcopenia, thus increasing the risk of fall, and finally the risk of fracture. [34, 35, 36] Also, hypovitaminosis D is a contributor to metabolic disturbances as insulin resistance, hyperlipemia etc. [37, 38] The doses of vitamin D required for supplementation are usually two to three times higher in obese versus non-obese individuals due to fat accumulation. [39, 40]

Sarcopenic obesity

The loss of muscle mass and function is progressive since the age of 40 and accelerated after 60 years. [41, 42] Obesity is a contributor to muscle damage and decline due to fat accumulation and inefficient fuel utilisation by the muscle, namely sarcopenic obesity, regardless the age. [41, 42] The collateral contributors to this pathological status is represented by low 25-hydroxivitamin D levels and the presence of glucose metabolism anomalies. [43, 44] Overall, the weakness of muscles causes a higher risk of fall thus of fractures. [43, 44]

Type 2 diabetes mellitus

The metabolic anomalies are associated as seen in metabolic syndrome where obese individuals are also diabetics. [45, 46] The risk of fracture caused by type 2 diabetes mellitus is more evident in menopausal women. [45, 46] Type 2 diabetes is associates bone damage and high fragility fracture risk due to glycated proteins of the matrix, the changes of adipokines as leptin, increased cortical porosity, increased risk of fall due to blood pressure anomalies, visual disturbances, renal and peripheral nerves diabetes-associated conditions. [47, 48, 49, 50]

Chronic inflammation

The network between fat and bones includes anatomical aspects like high BMI associates high BMI or mechanical loading is protective for fracture, but also changes of the skeleton micro-architecture in obese subjects that differs with the skeleton site thus some types of osteoporotic fractures are more exposed. [51, 52] Moreover, the fracture risk is augmented via fat derived cytokines and chronic inflammation as seen in metabolic syndrome or abdominal adiposity. [51, 52]

Bariatric surgery

Even it seems logical that the weight correction though bariatric surgery might reduce the fracture risk in obese individuals, actually data from longitudinal studies pointed that, despite the procedure is life saving, it does not actually protect against osteoporosis. [53, 54] Why? Because of the changes involving the mechanical loading due to the weight decrease, of lower intestinal surface for nutrients absorption (including potential malabsorption), anomalies of gut-produced calcitropic hormones, and restrictive diets after surgical procedure etc. [55, 56] Even osteoporosis after bariatric surgery seems a small price to pay, the post-operatory fractures are currently regarded as a long term complication on patients of different ages. [57, 58]

Depression

A higher risk of depression has been reported in obesity. [59] This may further involve reduced physical activity, including decreased sun exposure with risk of hypovitaminosis D and other factors leading to higher risk of fall and fractures. [60] Some mediators anomalies (as well as antidepressants-related) including serotonin have been reported at risk of bone loss through peripheral changes of its concentration despite the fact that circulating 5-hydroxytriptamin has not been yet indicated as a useful bone turnover marker in daily practice and conditions with pathological increase of the molecule as neuroendocrine tumours are not conventionally on the list of secondary osteoporosis. [61, 62]

DISCUSSIONS

Fracture risk assessment

DXA (Dual-Energy X-Ray Absorptiometry) does not particularly reflect the fracture risk in obese individuals since high BMI is correlated with high BMD. [63] FRAX also uses as input BMI. [64] Bone turnover markers might be blunted in associated diabetes and dramatically increased after bariatric surgery. [65, 66] Also type 2 diabetic menopausal women may beneficiate from TBS (Trabecular Bone Score) analysis. [67] The assays of 25-hydroxivitamin D might also be useful. [68]

Current limits

Obese individuals are less likely to receive anti-osteoporotic drugs since they already have several non-osteoporotic complications requiring different therapies. [69, 70, 71] Also, if a specific advisable drug in these subjects should be used in order to treat osteoporosis and/or to prevent fractures is not clearly understood up to this moment which is that drug, and probably the therapy for osteoporosis should be done based on similar protocols as in normal weight subjects with osteoporosis. [69, 71] Moreover, higher doses of vitamin D are necessary in obesity. [69, 71] The importance of therapy in order to provide an adequate primary and secondary intervention regarding osteoporosis is essential since the complications of fractures may become more severe due to obesity co-morbidities. [69, 71, 72]

CONCLUSION

A high fracture burden in obesity should increase the level of awareness for practitioners of different medical areas due to multiple levels of complications and to the epidemiological impact of obesity.

Obesity impact on symptomatology associated with pelvic floor dysfunction

Mihai C. Dumitrascu[1,2], Adina E. Nenciu[2], Adrian Neacșu[1,3], Ana M. Oproiu[1,3], Adelina Popa[4], Catalin G. Nenciu[1,5]

Abstract: *The increasing incidence of obesity, a significant health problem worldwide, represents a major socio-economic burden with a high impact on the quality of life. It is considered a risk factor for multiple medical conditions. More than half of women from developed countries are overweight or obese, this comorbidity can affect them from puberty through the reproductive period and then in the menopausal period, involving multiple medical and surgical specialties. It has a significant impact on the onset of puberty, the menstrual cycle, ovulation, fertility rate, and pregnancy outcome. In postmenopausal women, obesity represents an important risk factor for breast cancer, endometrial cancers or polyps, fibroids, pelvic organ prolapse, or stress urinary incontinence in addition to a higher risk of post-operative complications and also to some types of fragility fractures, especially if diabetes mellitus is associated. Pelvic floor disorders include pelvic organ prolapse, urinary or fecal incontinence. Obese patients seem more affected compare with normal-weighted females. We introduce a single-center, retrospective study on 74 patients (admitted between 2016 and 2019) with pelvic organ prolapses that were referred for surgical correction, and further on they were evaluated after one month, respective after 6 months since procedure. On admission, the subjects, aged between 41-82 years (median of 57 years) showed a strong correlation between the symptomatology caused by the prolapse degree and obesity (40.54% of them), as it appears that the discomfort and symptoms are significantly higher in the women with higher body mass index. In the reevaluation form, the patients with obesity complaint more frequently compared to the non-obese females about urinary and colorectal distress and low sexual desire and interest. The use of surgical treatment for pelvic organ dysfunctions is a contributor to improved quality of life in adult obese females.*

Keywords: *pelvic organ prolapse dysfunction, obesity, prolapse degree, body mass index, menopause, reproductive age*

INTRODUCTION

Obesity is one of the most severe health issues in developed and developing countries contributing to more than 4 million deaths each year [1]. It is by far the most frequent comorbidity severe pathologies and represents a major socio-economic burden with a high impact on the quality of life because of the disease itself, associated conditions, and impair the outcome of apparently non-connected conditions like abdominal surgery or procedures for gynecological diseases [2]. Excessive weight in the female population of reproductive age interferes with puberty, menstrual cycle, ovulation, fertility rate, abortion rate, pregnancy outcome, perinatal complications, and increased risk of severe infections [3-6]. Also, it is a risk factor for endometrial cancer, breast cancer, and uterine fibroids [7, 8]. It might

represent a poor prognosis factor in other malignancies like ovarian or color-rectal types [9, 10]. Most cases of obesity are associated with elements of metabolic syndrome like dyslipidemia, high blood pressure, and type 2 diabetes mellitus, also associating high serum uric acid, chronic inflammatory syndrome, anomalies of bone turnover markers, damage of coagulation profile, and mineral metabolism including hypovitaminosis D [11-14]. Obesity also may be secondary to endocrine tumors like adrenal – and pituitary neoplasia (for instance, Cushing syndrome, acromegaly, etc.), also associating anomalies of glucose profile, higher risk of some other tumors, poor wound healing, etc. [15]. Other causes of obesity and glucose profile anomalies are related to pancreatic tumors (somatostatinoma, glucagonoma, etc.) with heterogeneous manifestations [16-18]. Recently, obesity has been linked with a higher risk of fragility fractures, even though estrogens (including those derived from adipose tissue, not only of ovarian origin) are traditional elements of bone protection and that bone mineral density is directly correlated with body mass index [19, 20].

Pelvic floor dysfunction affects both females of reproductive age and post-menopausal, and it includes pelvic organ prolapse and urinary incontinence are significantly influenced by obesity [21]. Urinary incontinence is associated with increased intra-abdominal pressure caused by central obesity and is related to the period that women had had excessive weight [22]. Systematic studies regarding the effect of obesity on urinary incontinence and the results of surgery on this pathology showed that one of the main causes of decreased surgery effectiveness is represented by excessive weight [23,24].

Similarly, many studies had found a higher prevalence of pelvic organ prolapse among women with excessive weight especially morbidly obese and severely obese patients [25]. Unfortunately, the tissue damage from the pelvic floor caused by excessive weight is irreversible, as the cystocele, rectocele, or uterine prolapse does not reduce after weight loss [26]. Pelvic organ prolapse progresses with aging and has a low progression rate after menopause [27]. Some authors consider that the incidence of pelvic disorders will increase by 46% by 2050 [28].

Several surgical treatments for pelvic organ prolapse and stress urinary incontinence are known but many variables can influence the outcome. These are represented by prolapse degree, symptomatology, lifestyle, age, body mass index, sexual activity. This type of pathology, the treatment required, and the correlated risk factors have an important impact on the quality of life.

Obesity is particular comorbidity that is found in many patients with pelvic floor disorders. Obese patients can associate severe life-threatening pathologies but in the meantime, they can present sexual dysfunctions, pelvic organ prolapse, modified bowel movement, or urinary incontinence [29]. Pelvic floor dysfunctions are correlated by themselves with poor quality of life, modified bowel movement, modified urinary pattern, or sexual dysfunction. Obesity is correlated with an increased risk of urinary incontinence between 20 and 70% proportional with the body mass index [30]. Urinary stress incontinence is, without doubt, more frequent in obese women and it is demonstrated that bodyweight loss will lead to decreasing in the number of episodes [31, 32]. In the literature are reported studies in which up to 40% of patients admitted for pelvic organ prolapse presented with a high body mass index [33, 34]. Persisting and progressive obesity were associated with progressing prolapse degree but weight loss was not associated with significant improvement of the prolapse degree [35].

Studies have shown that obesity influences postoperative evolution. A poor outcome with anatomical and functional failure after surgery was associated with obesity, multiple vaginal deliveries, and the intensity of the symptoms before surgery [36].

MATERIALS AND METHODS

This study aimed to evaluate the influence of obesity on women with pelvic floor dysfunction that underwent surgery in our clinic between January 2016 and December 2019. It was designed as a retrospective study in women with pelvic organ prolapses who had clinical post-operative follow-up at 1 month and 6 months. The patient data collected included age, body mass index, number of births, hormonal status. The patients agreed to anonymously use their medical data during hospitalization for surgical procedures and during follow-up.

The pelvic floor disorder was evaluated before intervention for every patient with the Pelvic Floor Impact Questionnaire (PFIQ 7) which evaluates three aspects: Urinary Impact (UIQ-7), Colorectal-Anal Impact (CRAIQ-7), and Pelvic Organ Prolapse Impact (POPIQ-7) and with Pelvic Floor Distress Inventory-20 (PFDI-20) [19]. The women responded to the questionnaire in the presence of the medical team and the responses were corroborated with the patient’s history.

RESULTS

There were evaluated 74 patients that underwent surgery and had completed the questionnaires before the procedure. We included all 74 women aged between 41 and 82 years with a median of 57 years to participate in this study. Most of the patients were above 50 years at the moment of surgery (70.27%) and only 29.73% under 50 years. Only 6 of the 74 patients were nulliparous, 27 had one child and 33 had 2 children. Only 8 patients had more than 3 children. The majority of the women had one or two children (44 patients). Of these women, 59.46% had a body mass index lower than 30 and 40.54% were obese with a body mass index higher than 30. The majority of women reached menopause (48 patients), of which 30 were non-obese. Stage I and II pelvic organ prolapse was presented in 26.67% of the obese patient and 56.81% of the non-obese patients. Stage III and IV were present in 73.33% of the obese women and 43.18% of the non-obese women. The mean body mass index for patients with pelvic organ prolapse III or IV was 30.95 (±0.83) in obese patients and 25.64 (±1.96) in non-obese patients. The demographic data are presented in Table 1.

Table 1: Demographic data

	Non-obese n=44	Obese n=30
Age	40 – 77 (mean 59)	41 – 82 (mean 52.5)
IMC	20.65 – 29.39 (mean 25.33)	30.07 – 33.26(mean 30.83)
Menopause	30	18
Parity		
- nulliparous	4	2
- 1 birth	17	10
- 2 births	19	14
- 3 and more than 3 birts	4	4
Pelvic organ prolapse		
- I or II	25	8
- III or IV	19	22

The symptomatology was evaluated with PFIQ-7, PFDI-20, and FSFI for sexual life evaluation. A high result in PFIQ-7 and PFDI-20 represents an increased discomfort (scales 0 to 300). These patients also have poorer sexual function. For the PFIQ-7 the mean value was 191.73 (±60.00) for obese women and 152.72 (±69.16) for non-obese women (p = 0.0034, t = 3.0248, df = 72). The PFDI-20 the mean value was 192.5 (±43.12) for obese women and 156.84 (±64.33) for non-obese women (p = 0.0097, t = 2.6535, df = 72). These values suggest a strong correlation in our patients between the symptomatology caused by the prolapse degree and obesity, as it appears that the discomfort and symptoms are significantly higher in women with higher body mass index. Women with high scores on PFQI and PFDI had high scores on sexual function FSFI. Sexual desire and interest were low on 56%, sexual arousal reduced by 61% and 71% reached orgasm less than half of the time or rarely. The data collected is shown in Table 2.

Table 2: Pelvic Floor Distress Inventory-20 and Pelvic Floor Impact Questionnaire – scores in obese and non-obese patients

Variable	Non-obese (n=44)	Obese (n=30)	P value
PFIQ-7	Mean = 152.72 S.D.=69.16	Mean = 191.73 S.D.=60.00	p = 0.0034 t = 3.0248 df = 72
PFDI-20	Mean = 156.84 S.D.=64.33	Mean = 192.5 S.D.=43.12	p = 0.0097 t = 2.6535 df = 72
Prolapse degree	I-II = 25 III-IV= 19	I-II = 8 III-IV= 22	

PFIQ = Pelvic Floor Impact Questionnaire (scale 0-300)
PFDI = Pelvic Floor Distress Inventory (scale 0 -300)

The 74 women were evaluated 1 month after surgery, with a period of 4-6 weeks of sexual abstinence. The reevaluation was realized 6 months after surgery. At the reevaluation, the patients with obesity (30%) complaint more frequently compared to the non-obese females (18%) about urinary and colorectal distress and low sexual desire and interest.

There was 55.41 % with high pelvic organ prolapse degree (III or IV), from which most were women with body mass index above 30 (22 patients, compared to 19 non-obese patients). The high pelvic organ prolapse degree does not correlate with the body mass index (p=3.7, df =39).

DISCUSSION

The prevalence of obesity in developed and developing countries is continuously increasing. Although it can be managed with many options, it remains one of the most difficult comorbidity to correct. In our study, obesity was not correlated with stage III or IV prolapse, but pelvic floor symptoms were associated with a body mass index higher than 30.

The literature that evaluates the association between pelvic floor symptoms and obesity contains various results. The main cause of different results can result from the methodology of symptoms evaluation and defining the prolapse degree. In our study, one of the limits is represented by the small lot of patients that reduces the power of the study.

Hendrix et all [34] included in their study 16,616 women, from which 14.2 had uterine prolapse, 34.4% cystocele, and 18.6% rectocele, and found a strong association between this pathology and parity and obesity. Whitcomb et al [37, 38] enrolled 1,155 women in their study and concluded that the prevalence of any type of pelvic organ dysfunction was highest in morbidly and severely obese patients (57% and 53%) compared to obese women (44%), but the degree of discomfort was not influenced by the degree of obesity. Another large study [26] that included 16,608 patients concluded that obesity is associated with the progression of the pelvic organ prolapse and the damage might be irreversible. Both obesity and pelvic floor dysfunctions are associated with low quality of life.

CONCLUSIONS

Although the data can be conflicting, the practitioner must evaluate the patient and discuss the optimal approach to obesity-related complications. Managing obesity, even if it is not always a priority, it must be taken into consideration. Results take time, but in correlation with surgical treatment of pelvic organ dysfunctions, the overall quality of life of these patients will be significantly improved.

Obesity is not related to individuals but to environmental conditions; from the perspective of obese patients

Mehmet E. Yuksel[1], Namik Ozkan[2]

Abstract: *Background: The Beliefs About Obese Persons Scale (BAOP) is used among non-obese people in English speaking countries to evaluate their opinions on obese people. Nevertheless, the data are scarce from the view of obese people. Therefore, we wanted to test BAOP on obese patients in order to evaluate their opinions from the perspective of obese patients.*

Methods: Between August 2019-June 2020, 115 (76.7%) female and 35 (23.3%) male, a total of 150 obese patients who were admitted to the general surgery department to be evaluated for bariatric surgey, were included in this study. Local ethics committee approval was obtained (2019/08-10). These obese patients were asked to fill out BAOP, which included 8 statements in which each statement was valued between -3 to +3 points.

Results: Mean score of BAOP within all obese patients was 34.87 ± 8.12 (range: 5-48). The average score of BAOP was 34.33 ± 8.60 (range: 5-48) in females and 36.62 ± 6.06 (range: 21-48) in males (p = 0.14). The frequency of the answers given by the male and female patients to the 5th statement, which was "Most obese people eat more than non-obese people", showed a statistically significant difference (p = 0.03).

Conclusions: Obese patients had higher BAOP scores compared to previous BAOP studies performed with non-obese people. Within this study, obese patients considered obesity as a condition which was not under their control.

INTRODUCTION

Obesity is a worldwide public health problem causing predisposition to diabetes, heart disease and malignancy such as breast and colon cancer [1-3]. In the United States, more than 20% of the population has obesity [4]. Moreover, the number of people with obesity is rapidly increasing in Turkey. Patients who suffer from obesity not only have health related problems but also experience weight-related discrimination [5]. Patients with obesity often claim that they are accused of lacking self-discipline, uncontrolled binge eating, sedentary lifestyle, inadequate exercise and laziness [6].

Until now, different kinds of measuring scales have been introduced to evaluate the thoughts and beliefs of non-obese people over obese people [7-14]. Allison et al. published the article entitled "The measurement of attitudes toward and beliefs about obese persons" in 1991 [15]. One of the aims of Allison et al. was to develop reliable measures of beliefs about obese people, thus The Belifs About Obese Persons Scale (BAOP) was generated. Furthermore, Dedeli et al. tested and confirmed the validity and reliability of BAOP to measure beliefs about obese people in Turkish speaking countries [16].

Most of these previous studies with BAOP were performed on non-obese people. Nevertheless, the data are scarce from the point of view of obese people. Commenting on somebody else without having the same or similar conditions might be easy, however comments of obese people are of utmost importance to identify and solve obesity related problems within the society. Moreover, medical doctors should not only present a patient-oriented

approach to investigate the causes of obesity and treatment options but also include patients in the decisions about their health [3, 17]. Therefore, we wanted to test BAOP on obese Turkish patients in order the understand their beliefs about obesity and obese people. For this purpose, we asked 150 obese patients, who were admitted to the general surgery department to be evaluated for bariatric surgery such as sleeve gastrectomy, to fill out BAOP.

METHODS

Between August 2019-June 2020, 115 (76.7%) female and 35 (23.3%) male, a total of 150 obese patients who were admitted to the general surgery department to be evaluated for bariatric surgey, were included in this study. Aksaray University Ethics Committee approval was obtained (2019/08-10). The patients with body mass index (BMI) between 25 and 29.9 kg/m^2 were regarded as overweight and patients with BMI 30 kg/m^2 and above were regarded as obese [5, 18]. In addition, BMI between 35–39.9 kg/m^2, 40-49.9 kg/m^2 and over 50 pointed out severe obesity, morbid obesity and severe morbid obesity, respectively [19].

These 150 obese patients were asked to fill out BAOP. The Beliefs About Obese Persons Scale is an 8-statement questionnaire [15, 16]. The participants were asked to mark each statement according to how much they agreed or disagreed with it, using a scale between, -3 to +3 points (-3: I strongly disagree, -2: I moderately disagree, -1: I slightly disagree, +1: I slightly agree, +2: I moderately agree, +3: I strongly agree). These eight statements are: “1. Obesity often occurs when eating is used as a form of compensation for lack of love or attention., 2. In many cases, obesity is the result of a biological disorder., 3. Obesity is usually caused by overeating., 4. Most obese people cause their problem by not getting enough exercise., 5. Most obese people eat more than non-obese people., 6. The majority of obese people have poor eating habits that lead to their obesity., 7. Obesity is rarely caused by a lack of willpower., 8. People can be addicted to food, just as others are addicted to drugs, and these people usually become obese.”

All of the statements should be responded by the participants by the help of BAOP scale. In BAOP, points given to each statement by the participant are summed up. This final number is added to 24 in order to reach a total score, which varies between 0-48 [9, 20].

Statistical analysis was performed using the SPSS 20.0 statistical package programme. Numerical variables were stated as the mean (±) standard deviation and medians (minimum–maximum). Categorical variables were stated as percentages. The chi-square test and independent samples t test were used to compare differences between two groups. The p values <0.05 were considered significant.

RESULTS

This study included 150 obese patients, 115 (76.7%) were female and 35 (23.3%) were male. The mean age of the patients was 38.68 ± 12.09 years (range: 18-66). The mean age of women was 37.81 ± 11.53 years (range: 18-66), while the mean age of men was 41.51 ± 13.59 years (range: 21-66) (p = 0.11). The mean BMI of the patients was 42.03±7.24 kg/m^2 (range: 30.10-65.30 kg/m^2). Average BMI was 42.29±7.20 (range: 30.10-64.30 kg/m^2) in women and 41.16±7.41 (range: 30.16-65.30 kg/m^2) in men (p = 0.42).

The mean score of BAOP within all obese patients was 34.87 ± 8.12 (range: 5-48). The mean score of BAOP was 34.33 ± 8.60 (range: 5-48) in females and 36.62 ± 6.06 (range: 21-48) in males (p = 0.14). The answers given by all patients, female patients, and male patients separately to the questions on the scale of beliefs about obese people are shown in Table 1, Table 2 and Table 3, respectively.

Table 1: The frequency of the answers given by the patients to the questions of the Beliefs About Obese Persons Scale

	Patients (n/%)							
Score	**Q-1**	**Q-2**	**Q-3**	**Q-4**	**Q-5**	**Q-6**	**Q-7**	**Q-8**
-3	23 (15.3)	10 (6.7)	12 (8)	8 (5.3)	19 (12.7)	4 (2.7)	14 (9.3)	14 (9.3)
-2	13 (8.7)	11 (7.3)	7 (4.7)	7 (4.7)	13 (8.7)	4 (2.7)	8 (5.3)	4 (2.7)
-1	8 (5.3)	16 (10.7)	10 (6.7)	13 (8.7)	9 (6)	7 (4.7)	11 (7.3)	12 (8)
1	34 (22.7)	31 (20.7)	23 (15.3)	28 (18.7)	21 (14)	21 (14)	37 (24.7)	25 (16.7)
2	24 (16)	37 (24.7)	29 (19.3)	32 (21.3)	20 (13.3)	28 (18.7)	29 (19.3)	29 (19.3)
3	48 (32)	45 (30)	69 (46)	62 (41.3)	68 (45.3)	86 (57.3)	51 (34)	66 (44)

†Q: Question

48 (32%) patients gave 3 points to the first question, while 8 (5.3%) patients gave -1 points. (The first statement with “Obesity often occurs when eating is used as a form of compensation for lack of love or attention” has been answered as “I strongly agree” by 48 (32%) obese patients). 45 (30%) patients gave 3 points to the second question, while 10 (6.7%) patients gave -3 points. However, the patients gave most frequently 3 points ‘’I strongly agree’’ to all questions.

Table 2: Replies of female patients to questions about Beliefs About Obese Persons Scale

Female Patients (n/%)								
Score	**Q-1**	**Q-2**	**Q-3**	**Q-4**	**Q-5**	**Q-6**	**Q-7**	**Q-8**
-3	17 (14.8)	8 (7)	10 (8.7)	8 (7)	15 (13)	4 (3.5)	13 (11.3)	11 (9.6)
-2	9 (7.8)	9 (7.8)	6 (5.2)	5 (4.3)	13 (11.3)	4 (3.5)	7 (6.1)	4 (3.5)
-1	5 (4.3)	13 (11.3)	7 (6.1)	12 (10.4)	5 (4.3)	7 (6.1)	10 (8.7)	10 (8.7)
1	26 (22.6)	23 (20)	18 (15.7)	21 (18.3)	16 (13.9)	17 (14.8)	25 (21.7)	18 (15.7)

†Q: Question

38 (33%) of the female patients gave 3 points, while 5 (4.3%) patients gave -1 points to the first question. Most of the female patients gave 3 points ''I strongly agree'' to all eight questions.

Table 3: Replies of male patients to questions within Beliefs About Obese Persons Scale

Male Patients (n/%)								
Score	**Q-1**	**Q-2**	**Q-3**	**Q-4**	**Q-5**	**Q-6**	**Q-7**	**Q-8**
-3	6 (17.1)	2 (5.7)	2 (5.7)	0	4 (11.4)	0	1 (2.9)	3 (8.6)
-2	4 (11.4)	5 (5.7)	1 (2.9)	2 (5.7)	0	0	1 (2.9)	0
-1	3 (8.6)	3 (8.6)	3 (8.6)	1 (2.9)	4 (11.4)	0	1 (2.9)	2 (5.7)
1	8 (22.9)	8 (22.9)	5 (14.3)	7 (20)	5 (14.3)	4 (11.4)	12 (34.3)	7 (20)
2	4 (11.4)	11 (31.4)	12 (34.3)	7 (20)	1 (2.9)	9 (25.7)	8 (22.9)	7 (20)
3	10 (28.6)	9 (25.7)	12 (34.3)	18 (51.4)	21 (60)	22 (62.9)	12 (34.3)	16 (45.7)

†Q: Question

While 10 (28.6%) of the male patients gave 3 points to the first question, 3 (8.6%) of them gave -1 points. Most patients (31.4%) gave 2 points to the second question. Twelve patients gave 2 points to the third question and the other 12 patients gave 3 points. None of the male patients gave -3 points to the fourth question and -2 points to the fifth question. None of the patients gave -3, -2 and -1 points to the sixth question. The seventh question was answered as 1 point and 3 points by 12 patients equally. Most of the male patients (45.7%) gave 3 points to the eighth question.

The frequency of the answers given by the male and female patients to the 5th question showed a statistically significant difference (p = 0.03). However, the frequency of their answers to the 1st, 2nd, 3rd, 4th, 6th, 7th and 8th questions did not show a statistically significant difference (p = 0.82, p = 0.89, p = 0.18, p = 0.35, p = 0.28 p = 0.32).

DISCUSSION

BAOP scale is used to evaluate the beliefs about obese people. A low score on BAOP suggests that obesity is controllable as obese individuals cause their obesity by themselves. Nevertheless, a high score on BAOP scale indicates a stronger belief that obesity is not under the control of the obese person [20, 21]. Moreover, lower BAOP score points out tendency towards anti-obese attitudes such as accusing obese individuals as lazy and deprived of self-control [22]. Mean score of 17.9 with BAOP scale was reported to be associated with anti-obesity attitude [21].

Sonneville et al. explored weight bias among 322 public health trainees by an cross-sectional online survey assessing explicit beliefs about the controllability of obesity using BAOP [8] The mean BAOP scores within public health trainees was 22.9. Relative to male students, female students had a stronger belief that obesity was not within the control of the individual (p = 0.03) [8]. Soto et al. performed BAOP scale on 528 students (250 medical students, 278 psychology students), where 56.3% of the participants were women. The average age was 20.7 ± 3.0. The mean BAOP scores were 18.6±5.7 and 16.6±5.5 in psychology and medical students, respectively. No differences were observed between BAOP scores of the participants related to age, gender or BMI [23]. Darling et al. investigated BAOP scale scores of 403 nursing students, 35 graduate education students, and 88 graduate social work students. BAOP scores were inbetween 14.35-25.39 which indicated that there was room for improvement for the belief that obesity was not under the individual's control. BAOP scores were not signifficantly different between male and female students. Moreover, Darling et al. reported that perception of one's own body as obese and having a friend or family member who was obese did not lead to more positive beliefs that obesity was not under the individual's control [3]. Usta et al. aimed to determine beliefs of 658 nursing students about obese people [9]. The 76.6% of the students was female and the mean age of the students was 20.63 ± 1.52. The percentage of the students who were overweight was 15.2%. In addition, 18.2% of the students claimed to have had discrimimation related to their weight. More interestingly, 17.5% of the nursing students did not want to get involved in daily care of obese patients. The mean BAOP score was 23.36 ± 0.83 (minimum 21.38, maximum 26). Usta et al. found out that nursing students who had a previous history of diet and regular physical exercise believed that obesity was controlled by individuals [9]. Kadar et al. tried to assess the obesity bias among 143 preclinical and clinical chiropractic students and 30 faculty members [24]. Average scores of BAOP scale were 31.68±5.19, 31.26±4.83, 27.93± 4.85 and 30.07±7.85 in the student and faculty member groups, respectively. BAOP scores of preclinical faculty group was significantly higher than each student groups. As a result, obesity bias was common among students and faculty members [24]. Yilmaz et al. aimed to assess whether there was prejudice towards obese people among 190 student nurses and 189 registered nurses using BAOP [14]. The most of both student nurses and registered nurses had negative beliefs about obese people. The mean scores of BAOP scale were 17.4± 4.8 and 15.7±5.8 in student nurses and registered nurses, respectively which revealed that both groups had negative beliefs about obese people [14].

Within our study, the mean score of BAOP within all obese patients was 34.87 ± 8.12 which revealed that obese patients considered obesity as a condition that was not under their control. In addition, we identified that majority of obese patients gave 3 points to each question of the 8-item survey as they strongly agreed. Therefore, obese patients within this study had higher BAOP scores compared to BAOP studies performed with non-obese people. The results obtained from this study revealed that non-obese and obese people had different opinions about the reasons of obesity. Morever, mean BAOP scores within our study did not differ statistically in relation to gender as male and female. Nevertheless, the fifth statement within BAOP which questioned if most obese ate more than non-obese people was replied by female patients statistically different from male patients (p = 0.03). Thus, this might be a clue pointing out the different eating habits of male and female obese patients.

Previous BAOP scale-related studies performed on non-obese people revealed low BAOP scores which indicated that obesity was related solely to individuals. Therefore, obese people were accused of lacking self-control, for example not controlling enough their eating habits. However, in our study, obese individuals reached high BAOP scores which indicated that obesity was not related to individuals but to environmental conditions. This discrepancy within the BAOP scale points of obese and non-obese individuals require detailed investigation of the beliefs towards obese people and reasons of obesity. We hope these results encourage our colleagues not only to present a patient-oriented approach to investigate causes of obesity but also include obese patients in the decision process of their further medical or surgical treatment options.

Occipital radionecrosis and neuroplasticity in astrocytoma

Carmen A. Sirbu[1,2], Octavian M. Sirbu[3], Alexandra E. Bastian[4,5]

Abstract*: Background: Late-delayed complications after radiotherapy (RT) results from an imbalance between cell lesions and the protective capacities of the CNS. Temozolomide (TMZ) after RT may represent a potent radiosensitizing regimen. Although radionecrosis (RN) of the anterior visual pathway has been documented, in our opinion this is the first report of reversible visual field loss associated with occipital lobe radionecrosis.*

Case observation: We report a patient who suffered a left lateral homonymous hemianopia one year after radiochemotherapy (RCT) for an infiltrative low grade fibrillary astrocytoma. The visual field deficit was completely reversible after one month. Visual field defects have been described after the use of conventional external beam therapy for lesions near the anterior visual pathway. The cortex is relatively spared after RT.

Conclusions: Given the new scientific data, we suppose that neuroplasticity may play a role in the reversibility of visual field deficit. At this time there is no proven treatment of radionecrosis. Homonymous hemianopia caused by occipital lesions are attributable to vascular disease and tumors, but take into account radiation effects. The risk of neurogenic visual loss must be factored into the decision to irradiate the whole brain.

Keywords: *fibrillary astrocytoma, temozolomide, radiation necrosis, visual recovery, neuroplasticity*

INTRODUCTION

Radiation therapy is an integral part of modern therapy in gliomas. Early or delayed side effects are taken into account in determination of the therapeutic algorithm of each patient. The combination of radiotherapy and chemotherapy further increases the vulnerability to side effects. In this context, we present the case of a young woman diagnosed with fibrillary astrocytoma. One year after combined radiotherapy and chemotherapy with Temozolomide, right occipital lobe radionecrosis with impaired vision appeared.

Although such cases cited in literature are irreversible, in this case, both visually campimetric deficit and occipital brain lesion were fully reversible.

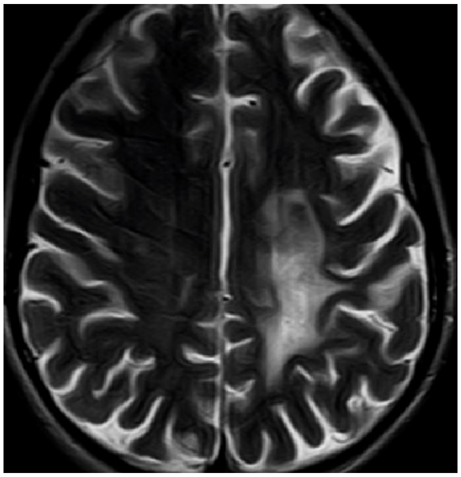
MATERIAL AND METHODS

A 21 years old, right-handed Caucasian female with mild idiopathic thrombocytopenia presented to the hospital with right sensory-motor hemiparesis. MRI revealed a subcortical low grade glioma in left rolandic region, extended to basal frontal and ascending parietal white matter regions, invading the dominant arcuate fasciculus, confirmed by brain biopsy.

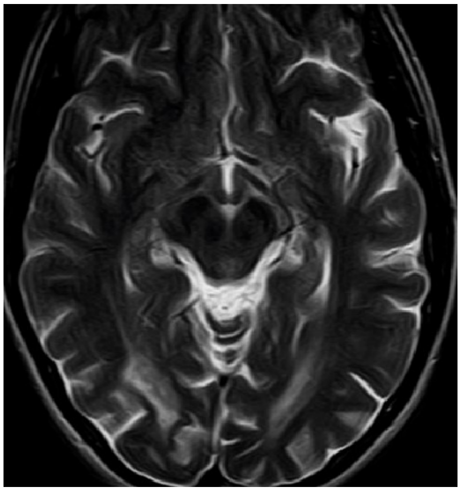
Given the infiltrative character of the tumor and its deep location, a surgical intervention is considered risky (the tumor invades left pyramidal fibers, thalamocortical fibers and superior longitudinal fascicle), especially without perioperative functional cortico-subcortical cartography procedures. Our patient undergoes 64Gy (photon teleradiation) radiotherapy for 6 weeks, followed by chemotherapy with Temozolomide (TMZ), 250 mg/day, 5 days/month for 6 months. Conventional MRI control reveals stationary aspect of the tumor (figure 1).

Figure 1



One year after chemotherapy, the patient insidiously develops left lateral homonymous hemianopia. A new conventional brain MRI shows a new 26/10 mm, irregular, non-homogenous, imprecisely defined right occipital lesion with hyperintense T2/Flair and isointense T1 signals, without contrast media enhancement. Fluorodeoxiglucose (FDG) PET-CT scan allows the differential diagnosis between tumor growth or radionecrosis and it reveals significantly decreased FDG uptake in the right occipital region, including the visual cortex (figure 2).

Figure 2

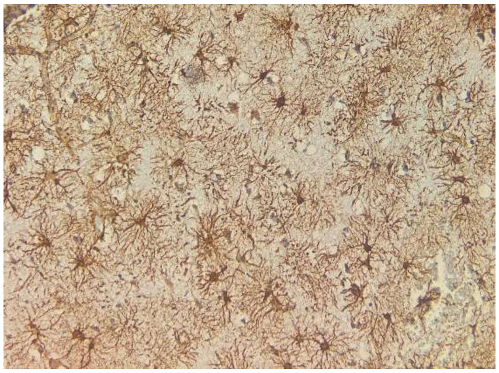


RESULTS

We conclude that the visual field deficit is the result of cerebral radionecrosis. The patient started a short period of corticoid treatment, with no improvements. One month from the first appearance of the hemianopia, it completely remitted and occipital right lesion were not visible.

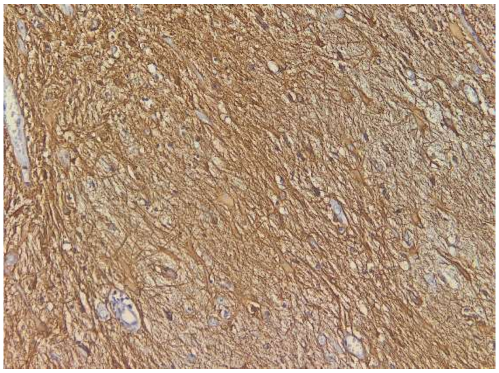
Worsening deficit in patients with cerebral tumors may suggest either tumor progression or its recurrence [1]. Imagistic methods reveal edema and enhanced lesions near the tumor area. On the other hand, radiotherapy may determine effects after months or years and these are called late-delayed reactions [2].

Figure 3



One of them is radionecrosis that occurs by vascular changes and ischemia, increase of capillary permeability and cerebral edema. Due to capillary permeability disturbances, adverse reactions of chemotherapy appear earlier and are more severe (figures 3, 4). Necrosis can be a result of radio and chemotherapy combination [3].

Figure 4



Temozolomide (TMZ) amplify the answer to radiations through DNA modifications and apoptosis [4]. TMZ combined with radiotherapy, enhances blood-brain barrier damage, leading to increased concentrations of therapeutic agents [5].

DISCUSSIONS

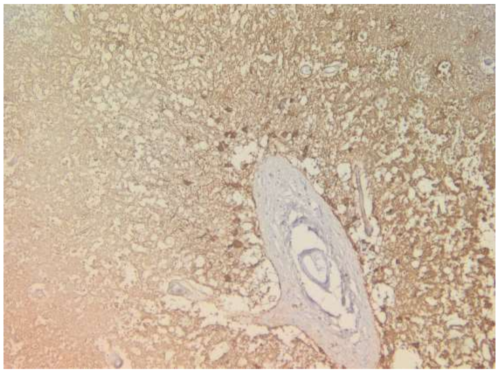
Few things are known about radionecrosis because it is difficult to differentiate from the tumor relapse with imaging techniques [6] and because the rate of surgical secondary interventions and brain autopsies are low in these patients [7].

In a study of 426 patients presenting glioma, Ruben and co. prove that the average time for the first appearance of necrosis is 11.6 months [8]. Also, adjuvant chemotherapy rises to over 4 times the cerebral necrosis risk. Peterson and co. reported a 2.5% incidence of radionecrosis, 8-31 months post-radiation, in a study including 200 patients with radiated and chemo-treated cerebral tumors [9]. So, as many have already demonstrated, chemotherapy has an amplifying effect in cerebral radionecrosis development. The incidence of radionecrosis is slightly raised in anaplastic oligodendroglial tumors than anaplastic astrocytomas and this is an argument for glial theory and its role in radionecrosis occurrence.

Things are even more complicated because the edema associated to this pseudoprogression is as symptomatic as the tumor actually progresses [10]. Conventional MRI (T2 and T1 with contrast) is limited in differentiating between tumor relapse and RT induced necrosis. Unfortunately, in many Gad positive lesions that occur after combined treatment, there are necrosis lesions and viable tumor cells and molecular magnetic resonance imaging of endogenous proteins and peptides are not for current use [11]. Diffusion MRI measures the mobility of water from tissues into the cells. After treatment, tumor cells are dehydrated and have a high apparent diffusion coefficient (ADC). Decreases of ADC indicate high cellularity [12]. Magnetic Resonance Spectroscopy detects tumor metabolites from tissues (choline, creatinine, lactate, lipids, N-acetyl aspartate) and is more sensible [13]. Dimensional spectroscopy has superior sensitivity indicating a relapse based on raised choline/NAA and choline/creatinine ratios [14].

18-Fluorodeoxyglucose PET scan is useful for differentiating between radionecrosis and recurrence and is 81-86% sensitive and 40-94% specific [15]. Still, false positive results have been encountered in non-malignant inflammatory processes, electric epileptic seizures and healing processes up to 3 months post-surgery. Even though, radionecrosis activates healing mechanisms and raises the glucose metabolism. This is why MRS is superior. There are some mechanisms that can explain postradiation necrosis: DNA modifications, coagulation factors imbalance with thrombosis facilitation [16]. The main mechanism of radionecrosis is associated with oligodendroglia injury or vascular endothelial damage (figures 5, 6).

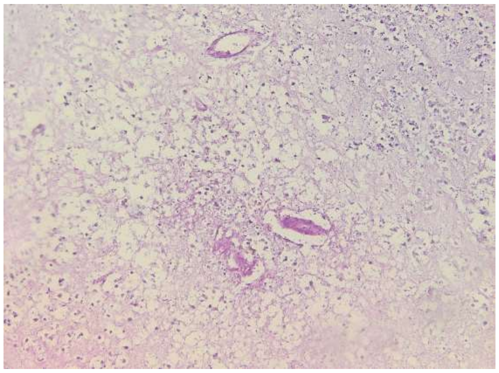
Figure 5



As a result, white matter tissue is often affected than gray matter tissue. Cytotoxic edema and tissue necrosis are the consequence of imbalance between tissue plasminogen activator and urokinase plasminogen activator.

But an autoimmune mechanism may be also involved.

Figure 6



Anterior visual pathways necrosis was well documented, especially in pituitary tumors, craniopharyngioma, parasellar meningiomas or optic nerve tumors [17]. In generally, visual field defects occur after one or more years after the radiotherapy stopped. Corticosteroids, surgery, bevacizumab and Hyperbaric Oxygen Therapy (HBO) are all possible good treatment options for symptomatic RN. The treatment goal is to provide the patient with resolution of neurologic symptoms, with the least toxicity and invasiveness [18]. Corticosteroid therapy was used to diminish the cerebral edema and cytokine release after radiation. Hyperbaric oxygen is considered to be useful in raising the tissular oxygen supply and for initiating tissue healing.

Diffuse, infiltrative, low grade gliomas (LGG) represent a clinical, histopathological and molecular distinct group with a very controversial management [19]. LLG patients may survive up to 20 years from the moment they were diagnosed, but there is the risk of tumor evolution into higher grades, eventually leading to neurological deficits and death [20]. Diffuse astrocytomas include the fibrillary, gemistocytic and protoplasmic types [21]. The fibrillary one is the most widespread and it presents a homogenous cellular population and moderate uncharacteristic nuclear modifications. Mitosis rate in grade II OMS astrocytomas is very small [22]. Clinically, the patient presents epileptic seizures, focal deficits occurred after many years and intracranial high pressure, especially in the subtentorial and intraventricular location. Conventional MRI is useful for guiding the biopsy and the resection, for radiotherapy and treatment monitoring. The usual method is MRI without contrast media, but when we add contrast it reveals changes in tumor grade transformation, better. In LGG spectroscopy shows high choline (high turn-over) and low NAA, reflecting neuronal loss [23]. Even though, similar results can be seen in non-tumor lesions. MRI is used rather for guiding the biopsy in an intense active area than for monitoring the evolution. 18 Fluorodeoxyglucose PET scan has a limited value as long as LGG indicates a low caption comparative to normal cortex [24]. The role of PET-FDG is, however, demonstrated in differentiating radionecrosis from tumor recurrence. More frequently used are [11C] methionine-PET scans given the fact that methionine is captured by tumor cells showing their proliferation process, thus giving a better contrast. PET-MET is also used for differentiating LGG from non-tumor lesions [25].

Neuroplasticity defines the ability to regain function after a neuronal lesion due to neuronal structures that take over the function of the damaged area and to nervous tissue reorganization (that is based on formation of new connections between neurons and/or new cell synthesis). The theory imposed in 1920 by S. Ramon y Cajal (which stated that once the development stopped, growth and regeneration of the axon and dendrites irrevocably stop) is torn down discredited by present scientific data [26]. Altman and co. showed the ability of some brain areas (such as hippocampus and olfactory bulb) to generate new neurons and they called this process neurogenesis [27]. Later, proves appeared that shown this process is influenced by factors like age, stress, physical condition [28].

Multipotent stem cells divide periodically in our brain giving birth to other stem cells or to adult cells. The newly formed stem cells move into areas that allow maturation. Approximatively 50% of them will die without reaching maturity. The others will become glial cells or neurons depending on the necessities of the brain area where they migrated. Fred H. Gage, emphasized in his review, that the necessary time for a stem cell to become functional and adapted to brain is about a month [29]. In this way we could explain full recover of the patient with left lateral homonymous hemianopia a month after the debut. A series of growth neuronal factors play an important role in keeping stem cells alive, mature and functional. Regaining cortical functions can be somehow explained by reorganization of cortical areas [30]. This process takes also place in the areas near the lesion or near the contralateral homologous cortex. Visual cortex reorganization after focal lesions implies plasticity mechanisms accompanied by excitation/ inhibition imbalances and changes in dendritic and axonal divisions [31]. Studies demonstrated a decrease in GABA inhibition and a growth of glutamate answer mediated by NMDA receptors in adjacent areas with the afflicted visual cortex [32].

CONCLUSIONS

Combined radiation and chemotherapy rises many times the cerebral necrosis risk, which may occur months or years later. Patient management should use specific and sensitive diagnostic tests. The differential diagnosis between tumor recurrence and radionecrosis is very important. Based on this differentiation, therapeutic attitude is different. For diagnosis certainty, tumor molecular biology tests are very useful, especially that current imaging techniques still cannot make a clear distinction. Low-grade gliomas should be better supervised by complete excision of the tumor, where the situation allows. Other therapeutic interventions, like chemo and radiotherapy, especially in the early years of evolution, should be used with caution, given their unpleasant effects. Radionecrosis should be treated promptly with corticosteroids, surgery, hyperbaric oxygen or bevacizumab.

Also, we need a plan for neurorehabilitation that assist in the neuroplasticity. All these compete to increase life expectancy and quality of life.

Oncological follow-up after radical prostatectomy

Dragoș Marcu[1], Dan Spînu[2], Dan Mischianu[1,2], Bogdan Socea[3,4], Ioana Oprea[5], Ovidiu Bratu[1,2]

Abstract: *Radical prostatectomy is the gold standard treatment for patients with localized prostatic cancer, but often the pathological diagnosis reveals a locally advanced stage.*

The aim of this paper is to present the oncological follow-up after radical prostatectomy on a group of 42 patients, patients which have been diagnosed after surgery with a more aggressive stage, locally advanced PCa. Over a period of four years 136 patients have undergone radical prostatectomy. The pathological examination has established that 42 patients presented extracapsular invasion and/or lymph node invasion. 18 patients (pT3-4N0M0) have undergone radiotherapy alone and 24 patients (8 pN1 and 16 pT3-4N1M0) have received androgen deprivation therapy in association with radiotherapy. Over the next two years 15 patients presented biochemical recurrence. For these patients chemotherapy was initiated, but in two cases PSA increase has been observed during periodic evaluation. Although it is not uncommon that postoperatively the histopathological examination establishes a more aggressive disease stage than that established before surgery, radical prostatectomy remains the solution for the localized prostate cancer, solution that can be boosted by radiotherapy and/or androgen deprivation therapy.

Keywords: *prostate cancer, oncological follow-up, complications*

INTRODUCTION

Prostate cancer is one of the most frequent, if not the most frequent neoplasic pathology encountered in men with ages over 60 years, its incidence increasing with age. The steady growth of life expectancy, due to a healthier life-style that more and more people tend to adopt, will automatically lead in the fallowing decades to a higher rate of prostate cancer detection [1-3].

Since its introduction, more than 20 years ago, prostate specific antigen (PSA) screening has significantly increased the number of patients diagnosed with localized prostate cancer.

The discovery of this marker at the beginning of the 1970s by Dr. Ablin and his colleagues has radically changed, in a good manner, the prognostic and the lives of the patients who suffer from this disease, but it took almost two decades to approve its use as a screening marker.

Before the FDA approval and introduction of the PSA as a tool to evaluate the treatment response and disease recurrence in 1986 and later in 1994 as a screening test for prostate cancer, the patients were usually diagnosed in advanced stages, with metastatic disease, associating a poor prognostic, less than 5% of the patients being curable [4].

Currently, due to early detection of prostate cancer,

[5] Intensive Care Unit, „Dr. Carol Davila" University Emergency Central Military Hospital, Bucharest

the curability rate of this pathology has significantly improved, the patients being diagnosed more frequently with lower disease stages, thanks to PSA screening. Radical prostatectomy among other therapeutical options (radiotherapy, brachytherapy) offers good disease control and even good cure rates, with low rates of local recurrence.

Radical prostatectomy is the most frequent therapeutical option used in the management of patients diagnosed with localized prostate cancer and with a life expectancy that is estimated to be higher than 10 years, being considered the gold standard treatment for this stage of disease [5]. Often, despite the fact that the preoperative evaluation establishes a localized stage, the postoperative pathological examination reveals a more advanced stage of prostate cancer.

The purpose of this article is to present the oncological follow-up in a group of patients diagnosed after radical prostatectomy with a locally advanced prostate cancer stage, after initially establishing a localized stage during the preoperative evaluation.

MATERIAL AND METHODS

We have retrospectively analyzed the experience of our clinic regarding open radical prostatectomy for localized prostate cancer and we have encountered that over a period of four years, from January 2013 to January 2016, we have performed 136 radical prostatectomies. Only the patients diagnosed during the preoperative evaluation with localized prostate cancer have been included in this study.

We have analyzed the PSA value, the result of the pathological examination after prostatic biopsy, pre- and postoperatory staging and Gleason score and as well as the short and long term oncological results and complications.

The preoperative diagnostic of prostate cancer was established by transrectal ultrasound prostate biopsy, this procedure being done in patients who presented repeated PSA values above the upper limit of the PSA reference interval or for the patients who presented a clinical suspicion of prostate cancer during digital rectal examination. After the pathological examination confirmed the cancer diagnostic all the patients have undergone pelvic contrast MRI and bone scan.

The prostatectomy was performed 6 to 8 weeks after the transrectal biopsy and 12 weeks after transurethral prostatic resection (TUR-P), for the patients diagnosed with prostate cancer after the pathological examination.

The postoperative evaluation was done at one month after the surgery and afterwards periodically at three months in order to evaluate the PSA level, the urinary continence status and erectile function. Biochemical recurrence was defined as two consecutive increases of the PSA level over 0.2 ng/mL.

RESULTS

The mean age of the patients included in the study was 63.09 years, varying between 51 and 78 years. The number of the prostatic tissue fragments harvested during prostatic biopsy puncture ranged between 6 and 12, being higher in saturation biopsy (24 to 32 fragments).

The mean operative time was 130 minutes, ranging between 100 and 300 minutes. Intraoperative bleeding has decreased over time, due to increased surgical experience, from 1500mL (in the first prostatectomies) to less than 200 mL in more recent surgeries. No major complications have occurred during the procedure.

As early postoperative complications we report macroscopic hematuria in less than 10% of the cases, wound infection (4%), prolonged lymphatic drainage in 8% of the cases and anastomotic fistula in 3 patients. Regarding the late postoperative complications (one year after the surgery) we have encountered: urinary incontinence, erectile dysfunction and lower urinary tract symptoms (LUTS).

The degree of urinary incontinence was evaluated periodically at one month after the surgery and afterwards at 3, 6 and 12 months using the International Continence Society male questionnaire. The degree of urinary continence was established by the number of urinary pads used during 24 hours. Out of 136 patients who have undergone radical prostatectomy only 3 patients presented total urinary incontinence, during the postoperative follow-up, 38 patients being partially continent and 95 patients being completely continent. Complete urinary continence was defined as the absence of the need for urinary pads during 24 hours and as well as the absence of urinary leakage during daily activities.

Erectile function was evaluated using the IIEF- 5 questionnaire. It was noticed that 78% of the patients for whom we have practiced bilateral nerve sparing surgery and 30% of the patients with unilateral nerve sparing presented satisfactory erections. For the patients with erectile dysfunction we have recommended phosphodiesterase 5 inhibitors.

9% of the patients presented moderate or severe LUTS, due to urethral stricture or due to bladder neck sclerosis. These postoperative complications were managed endoscopically.

42 patients presented after the pathological examination extracapsular invasion and/ or lymph node invasion. Therefore these patients presented in fact locally advanced prostate cancer and not the localized stage that was established during the preoperative evaluation. 18 patients out of 42 with extracapsular invasion (pT3-4N0M0) have undergone radiotherapy alone and 24 patients with lymph node invasion (8 patients with pN1 and 16 patients with both extracapsular and lymph node invasion) have undergone radiotherapy and androgen deprivation therapy (complete androgen blockade for two years).

15 patients presented successive increases of the PSA value at more than 2 years after treatment initiation, cases for which chemotherapy was recommended. 2 patients presented castration-resistance prostate cancer. Their therapeutical management consisted in bilateral orchiectomy and anti-androgen therapy. Two patients out 15 were resistant to the chemotherapy.

DISCUSSIONS

PSA detection has proven over the years to be a vital, cheap and reliable investigation for the detection of prostate cancer. Early PSA screening has led to a significant increase of the rate of patients diagnosed with localized prostate cancer, nowadays approximately 90% of this patients being curable [6].

Several studies have compared over the years the efficacy of radical prostatectomy and radiotherapy in patients with localized prostate cancer and have concluded that both therapeutical options provide good results regarding the recurrence free survival, cancer specific survival, overall survival and biochemical recurrence, especially for the low risk and intermediate risk patients [7-10]. In a study comparing the efficacy of radical prostatectomy versus intensity-modulated radiotherapy, Aizer concluded that for the high risk patients the radiotherapy approach provided better results when compared to the radical prostatectomy group. No significant differences were found between these two types of treatment for the low risk and intermediate risk patients [11].

Schreiber et all reported a better biochemical control for the patients with high risk localized prostate cancer for whom radiotherapy was the treatment of choice when compared to the radical prostatectomy group after a follow-up period of 6 years (67.4% RT vs 41.3% RRP). Regarding the low and intermediate risk groups he reported no significant differences between radiotherapy and radical prostatectomy, despite the fact that in both risk groups radiotherapy presented initially better results. The rates of biochemical control after 6 years for low risk and intermediate risk were 90.3% and 82.6% without any salvage therapy, while for the radical prostatectomy group the rates were 85.6% and 59.7% without salvage radiotherapy and 90.3% and 74% with salvage radiotherapy [7]. Petrelli reported in a 2015 meta-analysis, a better overall and cancer specific survival in high risk patients treated with radical prostatectomy when compared to radiotherapy [12].

In a 2015 study regarding the comparative outcomes between radical retropubic prostatectomy, high dose rate brachytherapy (HDRBT), cryoablation and high-intensity focused ultrasound (HIFU) for localized prostate cancer it was concluded that HDRBT presented the worst outcomes (cancer control, biochemical recurrence, salvage treatment free rate and metastases free rate) when compared to the alternatives [13].

CONCLUSIONS

Radical retropubic prostatectomy is the gold standard in the treatment of localized prostate cancer and in some cases, in the locally advanced prostate cancer.

Radical prostatectomy provides a significant improvement of the survival rate, for the cases where the surgical indication and technique have been correctly established and carried out.

Although it is not uncommon that postoperatively the histopathological examination establishes a more aggressive disease stage than that established before surgery, radical prostatectomy remains the a solution for the localized prostate cancer, solution that can be boosted by radiotherapy and/or androgen deprivation therapy.

Life, freedom, and pursuit of happiness are mentioned in the Declaration of Independence and engraved in the quote "***think big, you can do anything***" that defines the American spirit. Health is the element without which (sine qua non) obtaining all these would not be possible, and which is essential in the longevity and quality of life. Health is a priceless good in the economic and social development and in supporting the economies and powerful democracies, both at the individual and at the population level. Moreover, health is important for the security and prosperity of the nation. "We hope that, during the elections for the Congress, in 2018, the candidates will first think about the American citizens, thus relaunching the American tradition "think big, you can do anything", by applying the spirit of the winner in the reform of the authentic healthcare services", affirmed the famous professor Eliot Sorel (Senior Scholar Healthcare Innovation & Policy Research, GWU School of Medicine & School of Public Health and Founder Conflict Management Section WPA) in his article "*Health: its importance in Life, Freedom and Pursuit of Happiness*", which was published online on April, 14 2017.

Health of people represents a priority both for the European Union. The EU's main objective regarding the public health is the improvement of the health state of the population and the prevention of the diseases. This objective is mentioned in article 168 of the Treaty regarding the Functioning of the European Union (the Treaty of Lisbon), which also offers examples of activities which the EU cannot undertake in order to achieve the objectives. Among these, the following can be mentioned: controlling epidemics, studying their causes and their prevention. EU also supports drugs abuse control, as well as the efforts of the member states in the fight against smoking and of excessive alcohol consumption. Another objective is the increase in the degree of complementarity of the healthcare services in the border areas.

The remarkable progress of healthcare doubled by better life conditions continuously lead to a raise in the life expectancy of the people everywhere worldwide.

In contrast to this positive evolution, the diseases threatening the health of the people keep on developing, diversifying and, implicitly, the expenses and the effort to preserve an appropriate state of health continually raise and use a huge amount of resources that are hardly sustained.

In this context, a new global medical concept, "One Health", started being organized worldwide, at the same time trying to find the causes for the evolution of the diseases and their spreading, looking to recommend the adequate solutions in the fields in which the human health is more and more assaulted.

Among the accomplishments in this field, the International Center for Food Chain and Networks

Research – **FoodNetCenter Bonn**, founded in 2006 in the University of Bonn, can be reminded. The center's main objectives are the following: interdisciplinarity, contribution to the evolution of the university profile, research, and development.

Moreover, it has three *Focus Groups*, which are base units for the organizational structure, fully integrated in the University: *Food Waste*, *"One Health"* and *Responsible system innovation.* The main common problem of all the three Focus Groups is the fact that the food request will double until 2050 and, the interdisciplinary groups of interest could try to solve the problem by contributing to a responsible and solid production, processing, and food consumption.

The University of Bonn (the International Center for Food Chain and Networks Research – FoodNetCenter Bonn) has involved from the beginning in founding, in 2015, the Education and Qualification Alliance – ***EQA,*** which acts at the level of the network by supporting the knowledge suppliers, the standardization and certification organisms in promoting quality, food safety, sustainable development, social and corporate responsibility and, ***"One Health",*** only one Health for People, animals and the Environment, represents the new global concept that reunites preoccupations of the specialists in all the fields that threaten health, including Food, Nutrition and Occupation, with two main action directions: Primary Prevention of Life and Life Post-Therapy.

From the initiative, giftedness, and generosity of some important personalities in the social, cultural, and scientific life, the Association **"ONE HEALTH-New Medical Concept"** Romania was founded in Romania in May 2015, being an associated member of the ***Federation*** of the ***European Academies of Medicine*** (FEAM) (www.onehealth.ro).

In our country, as well as in others, the *"One Health"* concept implies the summing of the efforts and the achievements that *Human Medicine, Veterinary Medicine, Environment Medicine, Food and Nutrition Medicine, Occupational Medicine, Compared Medicine (zoonoses and compared oncology) record with the Primary prevention of life, promoted as a major vector*, together with their application in medicine, while desiring a strong health state with costs as low as possible.

The objectives of the activity are the following: creating a national network of research and development and implementation in the field of One Health, which is internationally affiliated; promoting and developing scientific research projects; establishing professional and organizational relationships with research-development and education structures; educating the people who work in the field of compared medicine, food safety, environment medicine and bioeconomy, as well as cooperation in the scientific academic field; organizing events and activities that would favor the exchange of scientific ideas in the field of compared medicine, food safety, environment medicine and bioeconomy; implementing new scientific guidelines of the involvement of "life environment" in the "one health"-human medicine-veterinary medicine-environment medicine relationship, in order to achieve the concept of eco-prevention and eco-therapy in the initiative of developing the strategy of primary prevention of diseases in humans and animals; promoting postgraduate education in the field of compared medicine and stimulating the activity of technological transfer in the field of compared medicine.

In order to achieve these goals, an efficient and continuous implementation and international recognition, the Association founded departments on specialties such as *Department of Management, Bioeconomy and Law; Department of Compared Medicine; Department of Human Medicine; Department of Veterinary Medicine; Department of Environment Medicine; Department of Food Safety; Department of Zoonoses; Department of Pharmaceutical Production and Biological Drugs; Department of Scientific Research; Department of Education; Department of Non-Conventional Therapies; Department of Compared Oncology; Department of Radiology in Medicine; Department of Phytopathology* and *Department of Accreditation*.

ONE HEALTH New Medical Concept Association has already organized its first prestigious scientific meeting, One Health National Conference 2017, in Târgu-Mureș, with the support of the University of

Medicine and Pharmacy in Târgu-Mureș, the Academy of Medical Sciences in Romania, Spiru Haret University, Mureş County Council, College of Physicians in Romania and ***Romanian College of Veterinarians***, the President of Honor being Andre Laurent Parodi – Academy of Medicine in France, and, the executive presidents being Acad. Nicolae Manolescu – President of OHNMC Romania, Prof. Leonard Azamfirei, MD, PhD – Rector of Târgu-Mureș University of Medicine and Pharmacy and Prof. Irinel Popescu, MD, PhD – President of the Academy of Medical Sciences in Romania. Next year, the Association will also organize "ONE HEALTH - 2nd European Inter-regional Conference, 5–8 September 2018, under the high patronage of the Government of Romania. The organizers of the event will be Spiru Haret University, Bucharest; ONE HEALTH - New medical concept Romania and the University of Veterinary Medicine Hungary – Budapest. The area of interest will be the following: Environmental medicine; Antimicrobial resistance; Comparative medicine; Food safety and nutrition medicine; Comparative oncology and Zoonoses. The Presidents of Honor will be Prof. George GRIFFIN, MD, PhD, President of the Federation of European Academies of Medicine (FEAM) and Member of the British Academy of Medicine; Prof. Bernard CHARPENTIER, MD, PhD, Past President of the Federation of European Academies of Medicine (FEAM) and Member of the French Academy of Medicine, Prof. André-Laurent PARODI, DVM, PhD, Honorary President of the French Academy of Medicine and Honorary Director of Alfort National Veterinary School, France, Prof. René CARLSON, DVM, PhD, Past President of the World Veterinary Association AVMA and Director of International Affairs, and the Executive presidents will be Prof. Nicolae MANOLESCU, DVM, PhD, Correspondent Member of the Romanian Academy, Correspondent Member of the French Academy of Medicine and President of the Romanian One Health New Medical Concept Association; Prof. Stefan CONSTANTINESCU, MD, PhD, Correspondent Member of the Romanian Academy, Professor at the Université Catholique de Louvain, Brussels, Belgium, Vice President of the Federation of European Academies of Medicine (FEAM) and Vice President of the Romanian One Health New Medical Concept Association; Prof. Peter SOTONYI, MVD, PhD, Rector of the University of Veterinary Medicine, Budapest, Hungary; Assoc. Orthodontic treatment and periodontal disease – between advantages and disadvantages

Ruxandra Voinea-Georgescu[1], Cristian N. Cumpătă[1], Mihaela Răescu[1], Mihaela J. Tuculina[2], Ionela T. Dascălu[2], Lelia M. Gheorghiță[2], Carmen Defta[3], Anca Gheorghe[2]

Abstract: *Orthodontic treatment and periodontal disease can have an inter-conditional relationship, particularly when the accumulation of bacterial plaque, favoured by orthodontic appliances and poor oral hygiene can cause periodontal inflammation. The objective of the study is to highlight the influence of the risk factors' polymorphism on the therapeutic response in periodontal disease. 64 patients with mixed or definitive dentition and poor oral hygiene were included in the study, of whom 22 patients followed treatment with fixed orthodontic dispensers, 22 patients were treated with mobile orthodontic braces and 20 were non-attendants. From all patients gingival crevicular fluid was collected and assessed, before and after applying a chlorhexidine-based gel antiseptic agent.*

Keywords: *periodontal disease, orthodontic treatment, chlorhexidine gel, gingival fluid*

INTRODUCTION

Periodontal disease inflicts a wide range of oral changes, ranging from gingival tissue inflammation to tooth loss. During some orthodontic treatment protocols patients may not to compliant to keeping a good oral hygiene, possibly due to the difficulties that certain orthodontic appliances may impose on efficient teeth brushing [1]. Microbiological patterns involved in the genesis of periodontal disease are more common in orthodontic treatment patients, so the bacterial plaque is left undisturbed for a long period of time around the orthodontic appliances and can grow in bacteria number and pathogenic potential. Microbial periodontal pathogens, especially Gram-negative bacteria, are more frequently found around fixed/mobile orthodontic appliances [2]. Periodontal disease may have different clinical forms, with a wide range of manifestations, from gum tissue damage to periodontitis, which can even lead to tooth loss in some cases [3].

The clinical manifestations and evolution of periodontal disease may vary in accordance with the intensity of the bacterial challenge. In orthodontic treatment patients, the periodontal tissues are also challenged by the orthodontic forces which generate teeth movement. During teeth movement, all periodontal structures, including the gingival, the periodontal ligament and the alveolar bone are under constant mechanical stress [4]. This mechanical stress can cause a decrease of the tissue's defensive capabilities. Combined with the increased bacterial challenge, caused by poor oral hygiene, this creates very favourable conditions for the onset of periodontal disease [5]. Consequently, a good understanding of the periodontal disease's existing aetiology and risk factors is required for a correct diagnosis and

treatment plan for a patient undergoing orthodontic therapy.

The objective of this study was to highlight the influence that certain risk factors have on the therapeutic response in periodontal disease in orthodontic patients and to assess the local impact that the use of an anti-plaque agent has in these patients.

MATERIAL AND METHOD

The study included a group of patients who were clinically examined and expressed similar symptoms during the first visit to the dental office. In order to collect the data obtained from the anamnesis, observation charts were prepared for each patient. The inclusion criteria used for the study were the following: (1) patients who were treated or not with orthodontic braces/mobile dispensers; (2) age 12-20 years; (3) the presence of mixed or definitive dentition; (4) the presence of gingivitis subjective and objective clinical signs (gingival bleeding, gingival oedema, halitosis). Following the clinical examination, a bacterial plaque index was calculated for the participating patients, its values being directly proportionate with the degree of gingival inflammation.

A total of 64 patients with mixed or definitive dentition and poor oral hygiene were selected, being divided into 3 study groups: (1) 22 patients carrying a mobile orthodontic device; (2) 22 patients with fixed orthodontic appliances and (3) 20 patients who did not require or have refused orthodontic treatment.

Before initial periodontal therapy (airflow cleaning and professional brushing) gingival crevicular fluid was sampled from the gingival sulcus of the participating patients. For sampling sterile paper, cones of 20 mm were kept for 30 seconds in the periodontal pocket/gingival sulcus, after the pre-removal of the supragingival bacterial plaque, in order to avoid contamination of the sample with supragingival bacteria. The collection and transport of the biological products and the stages of microbiological diagnosis were performed by the clinician and their assistant.

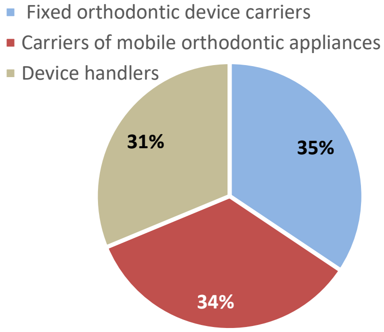
The results of microbiological investigations depend to a large extent on the quality of the sampling procedure, which needs to follow specific rules:
(a) the patient was informed about the aimed analysis and about the correct way of sampling procedure;
(b) the sampling instruments were sterile, disposable and adapted to the investigation;
(c) the pathological product was harvested prior to administration of any topical or general topical treatment; it is harvested from areas where it is most likely to find the bacterium that produced the infection;
(d) the outside of the container was disinfected if it has been contaminated during sampling procedure;
(e) the name of the patient and his provenance, the type of biological product, the date and time of collection was written on the container;
(f) each pathological product was accompanied by a bulletin containing information about the sample and the patient;
(g) transport was as quick as possible to the laboratory to prevent the degradation of the pathological product;
(h) transport media used ensured good survival of bacteria;
(i) for the oral cavity, the sampling procedure consisted in carefully cleaning the edge of the gum and tooth surface to remove saliva and food debris, afterwards a periodontal scalpel was used and the lesion secretion was removed;
(j) transport was carried out using an anaerobic transport system in less than 2 hours from sampling.

Microbiological tests were performed to detect aerobic and anaerobic gram-positive and gram-negative bacteria. After the initial periodontal treatment, the patients were randomly re-divided into two groups, as follows: (1) 12 patients with orthodontic devices (six fixed devices, six mobile devices) and (2) 12 appliance donors, who received applications of a chlorhexidine-based gel (Elugel 0.02%, Pierre-Fabre, France). The other 24 patients were only instructed for good oral hygiene and monitored. The ethical standards of medical research and GDPR (Global Data Protection) and the approval of the Ethics Committee of the Faculty of Dentistry of the “Titu Maiorescu” University in Bucharest were followed by the present study.

RESULTS

The distribution of the participating patients regarding orthodontic treatment type was similar between the patients with mobile and fixed orthodontic appliances (Figure 1).

Figure 1: Selection criteria: fixed/mobile orthodontic handlers/ carriers



The microbiological assessment revealed bacteria of the violet periodontal complex: (Veillonella parvula, Actinomyces odontolyticus), yellow complex (Streptococcus spp), green complex (Eikenella corrodens, Capnocytophaga spp.) red complex (Porphyromonas gingivalis, Tannerella forsythia, Treponema denticola) and of the orange complex (Prevotella intermedia/nigrescens, Micromonas micros, Campylobacter rectus, Fusobacterium nucleatum) (Figure 2). Compared to the microbial flora normally found in gingival tissue of healthy individuals with no periodontal problems, microbiological tests revealed the exaggerated growth of germs in the case of fixed carriers and a significant increase in the case of mobile carriers, as shown in Table 1.

Streptococcus spp, P. gingivalis, and F. nucleatum predominantly occured in fixed-bearer carriers, while Treponemma is constantly present whether or not the patient is treated with fixed or mobile devices. The Actinomyces spp were present within the saprophytic flora and does not develop during orthodontic treatment.

Figure 2: Bacteria type frequency in periodontal heath vs. gingival inflammation (%)

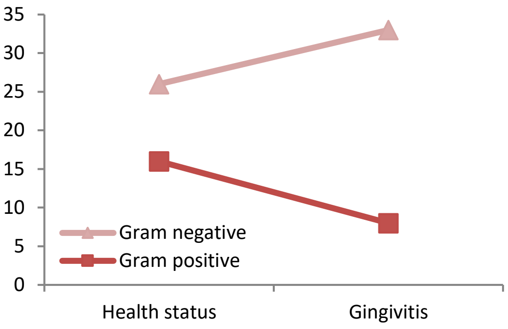


Table 1: Distribution of bacterial pathogens according to study groups

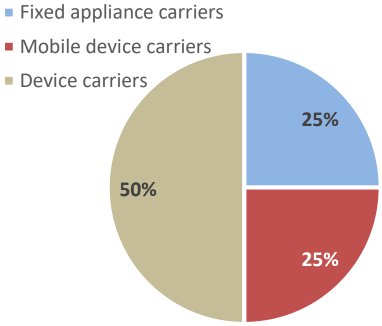
Pathogen	Health	Not carriers of orthodontic braces	Carriers of orthodontic braces	Carriers of mobile devices
Streptococcus	+++	+	+ ++	+ +
Actinomyces	+++	+	+	+
Veillonella	+	+	+	+
Aggregatibacter actinomycetemcomitans	-	++	+	?
Capnocytophaga	+/-	+/-	+/-	+/-
Treponeme orale	+/-	+++	+++	+++
Porphyromonas gingivalis	-	+	+++	++
Prevotella intermedia	+/-	+	+++	++
Tannerella forsythia	-	++	++	?
Fusobacterium nucleatum	+	++	+++	++

Figure 3: Patients treated with chlorhexidine-based gel antiseptic substance



Following the application of the chlorhexidine-based gel antiseptic substance to orthodontic patients, it was found that after two weeks the results of the microbiological analysis of the gingival sulcus exudate revealed a reduction of the number of pathogenic bacteria in the orthodontic treated subjects and their disappearance in the non-attendant devices (Figure 3).

For the patients who did not benefit from the application of chlorhexidine-based gel substance, it was found that for the orthodontic handlers the microbial flora was still highly present. After 30 days, when the patients were reassessed, it was discovered that the pathogenic flora disappeared in all patients treated with chlorhexidine-based gel antiseptic substance, both with orthodontic treatment or not.

DISCUSSION

According to the literature, a study by Al-Bazi et al. from 2016 demonstrated that the formation of dental biofilm is a result of the increase in the number of microorganisms on the tooth surface, which was found to be 2-3 times higher in patients under orthodontic treatment than in young people without orthodontic treatment [6]. Previous studies have shown that regular dental brushing and the use of dental floss alone do not decrease levels of S. mutans in patients treated with fixed orthodontic appliances [7]. In our study, subjects treated with mobile orthodontic devices, compared to healthy individuals without periodontal problems, revealed an exacerbated growth of germs in the case of fixed-bearer carriers and a significant increase in the case of the mobile-bearer carriers. Some bacterial species (Streptococcus, Porphyromonas, Prevotella and Fusobacterium) are found mainly in fixed-bearer carriers, while Treponemma is constantly present whether or not the patient is a carrier of fixed or mobile devices and Tannerella forsytia is absent in patients' exudates.

Different protocols have shown the ability of CHX (Chlorhexidine) to inhibit the formation of dental biofilm and to reduce plaque development [8]. Randomized, controlled clinical trials demonstrated the efficacy of 0.50% and 0.75% CHX to control gingivitis and bleeding in orthodontic patients, concluding that lower concentrations of chlorhexidine may reduce the risk of tooth colouring, without compromising its effectiveness level against pathogenic bacteria [9]. In our study, applying the chlorhexidine-based gel antiseptic substance significantly reduced the number of bacterial colonies in all patients of the study. However, antiseptic treatment should not replace dental mechanical treatment, but be applied in a complementary manner [10]. Combining mechanical treatment with local application of antiseptics gives statistically better results than each of them taken separately does.

CONCLUSIONS

Given the results of the study, we can conclude that for the patients treated with orthodontic appliances, either fixed or mobile, it is impossible to completely clean all oral surfaces and to decrease the number of microbial colonisation without the application of local antiseptics during the treatment. The results of the study can be used to prevent periodontal disease in patients with orthodontic treatment.

Osteoporosis and the fracture risk in systemic lupus erythematosus

Mihai L. Ciobîcă[1], Oana P. Ionescu[1], Bianca A. Săndulescu[1]

Abstract: *Osteoporosis is a systemic skeletal condition, characterized by a microarchitectural degradation of bone density and quality, giving low resistance and an increased risk of fracture. Osteoporosis is an important public health problem, with considerable medical, social and economic impact. Data accumulated in recent years demonstrate a significant incidence of osteoporosis in the group of patients with major collagen diseases; of these, Systemic Lupus Erythematosus (SLE) is the prototype of autoimmune disease in which osteoporosis and associated complications have a significant clinical impact.*

Although additional studies are needed to deepen the relationship between SLE - osteoporosis - associated fractures, we believe that these patients should be managed from the early stages of the disease.

Keywords: *systemic lupus erythematosus, osteoporosis, risk factors, fragility fracture, therapeutic principles*

INTRODUCTION

Osteoporosis is a systemic skeletal condition, characterized by a microarchitectural degradation of bone density and quality, conferring low resistance and an increased risk of fracture [1, 4]. Osteoporosis is a significant public health problem, with considerable medical, social and economic impact, through the associated costs. The prevalence of osteoporosis in Romania in the population over 50 years of age is 20.5% in women and 6.2% in men [1].

Osteoporosis is an asymptomatic disease. The main clinical manifestation and at the same time complication of osteoporosis is the fragility fracture. Worldwide, it causes over 9 million fractures annually, approximately one osteoporotic fracture every three seconds [2].

Classification of osteoporosis [1, 3, 4]:

- Primary osteoporosis: type I (postclimax) and type II (elderly).
- Secondary osteoporosis: occurs in association with other conditions or with the use of certain drugs.

Causes of secondary osteoporosis [3]:

- Endocrinological: thyrotoxicosis, hyperparathyroidism, hypogonadism, Cushing's syndrome, insulin-requiring diabetes, Addison's disease, sarcoidosis.
- Gastrointestinal: severe liver damage, primary biliary cirrhosis, gastrectomy, malabsorption syndromes.
- Metabolic and nutritional: hypophosphatemia, hypercalciuria, hemochromatosis, amyloidosis, parenteral

nutrition.

- Hematological disorders and neoplasms: hemophilia, thalassemia, myelomatosis, lymphoma and leukemia, tumors secreting PTH-like peptides.
- Inflammatory diseases: rheumatoid arthritis, systemic lupus erythematosus (SLE), etc.
- Others: chronic kidney disease, cardiovascular, neurological diseases, etc. [4].
- Medications: glucocorticoids (over 5 mg/day prednisone or equivalent, more than three months), anticonvulsants, proton pump inhibitors, heparin, antidepressants, etc.

This classification in primary and secondary is not delimited. Sometimes the causes of secondary osteoporosis can coexist with post-menopausal status or with aging.

Classical risk factors for osteoporosis

Modifiable risk factors:

- Nutritional deficiencies: Diet influences bone mass and risk of fracture. Nutrients with an important role in bone metabolism are calcium, vitamin D and, last but not least, proteins. Low protein intake is an essential determinant of bone mass. Malnutrition can increase the risk of falling both by affecting coordination and reducing the muscle strength [5-9].
- Physical inactivity: A significant cause of bone loss. It has been observed that forced immobilization in healthy volunteers or in patients with neurological disorders such as paraplegia, leads to decreased bone mineral mass. The negative effect of immobilization is much greater than the potential benefit of exercise on an already outpatient subject [10].
- Weight: A low body mass index correlates with a low bone mineral density (BMD), probably due to decreased peripheral estrogen production by adipose tissue and a lower mechanical load on the skeleton that metabolically influences bone composition [3].
- Smoking: After menopause, bone mineral density in women who smoke decreases by two percent/decade compared to non-smokers [12]. A much more significant loss of bone mass was observed in smoking men, especially in the femoral head. The risk decreases with smoking cessation but becomes significant only after ten years of withdrawal [13].
- Excessive alcohol consumption: Indirectly, influences the bone metabolism by decreasing protein and calcium intake, impaired gonadal function, mobility (increases the risk of fracture by falling), and directly, through the toxic effect on the osteoblast [3].

Non-modifiable risk factors:

- History of falls: Falls are the most common cause of osteoporotic fractures. The annual risk of falling increases by about 20% in women between 35 and 49 years and is over 30% in eldery men [14]. The risk of falling is directly correlated with the number of comorbidities (e.g., neurological disorders, cardiovascular diseases, urinary incontinence, depression, etc.). Also, medications such as hypnotics, sedatives, or antidepressants increase the risk of falling [14-17].
- Age over 65 or under 65 who associate several risk factors.
- Women: a higher risk of osteoporosis. Bone loss is 0.86-1.21% and increases after menopause, unlike men, where the loss is about 0.04-0.90% [18]. Despite this, secondary osteoporosis appears to be more common in men [19, 20].
- Fragility fractures in personal history: the presence of an osteoporotic fracture increases the risk of subsequent fractures. Thus, in both men and women who have suffered a distal fracture of the forearm, the risk of subsequent fractures of other skeletal regions is approximately doubled [21-24].
- Genetic predisposition: about half of the total bone mass, as well as bone architecture and geometry (elements relevant for bone strength), can be genetically determined [25, 26].

Preliminary data studied reveal a significant incidence of osteoporosis in patients diagnosed with collagen diseases. Of these, SLE is the prototype of autoimmune disease that predominantly (but not exclusively) affects young women, but also men. For this group of patients, osteoporosis is a frequent long-term complication.

With the progress of therapeutic strategies and the introduction of new effective treatments in SLE, organ complications are much better controlled, which has led to a significant increase in life expectancy. In this context, osteoporosis and associated complications have a greater clinical impact and the therapeutic attitude must focus on this aspect, from the early stages of the disease.

Regarding the method of objectification and osteoporosis diagnosis, there are several techniques for measuring bone mineral density, but the most common is using dual X-ray absorption (DXA). Bone densitometry provides two results: the T score, which provides the result by comparing the patient's bone density to a person with maximum bone density – a healthy 30-year-old, and the Z score, which compares the patient's bone density with that of a person of the same age to assess the degree of bone loss.

PARTICULARITIES OF OSTEOPOROSIS IN SLE

Osteopenia, defined as a T score between 1.0 and −2.5 in the spine and femoral head, has been reported in 25–74% of patients with SLE, while osteoporosis, defined as a T score less than −2.5, in 1.4–68% of patients with SLE in cohort studies [27].

Despite the large variability of epidemiological data, a significantly increased prevalence of low bone mineral density is recognized in SLE patients versus the general population.

Particular risk factors and mechanisms of occurrence

The etiology of bone density reduction and fractures is multifactorial, involving classical, disease-independent risk factors and particular risk factors. Among them, we mention:

- Inflammatory factors: Systemic inflammation contributes to bone loss by influencing the balance between bone resorption and osteosynthesis, causing an increase of osteoclasts activity. In addition, in the active forms of the disease, an increased level of tumor necrosis factor (TNF) and oxidized low-density lipoprotein (LDL) was observed, the latter interfering with the maturation of osteoblasts and activating T lymphocytes [27, 57, 58]. T lymphocytes involved in the synthesis of TNF and nuclear factor kappa B ligand receptor activator (RANKL) stimulate osteoclast differentiation [58]. A low complement C4 level (an indicator of disease activity) was considered a predictor of decreased bone density in the lumbar spine (Hopkins Lupus Cohort) [28]. A 5-year study showed a correlation between the frequency of disease outbreaks and the impact on bone density, confirming the hypothesis that systemic inflammation contributes to bone loss in SLE. In addition, more than half of diagnosed patients develop inflammatory nephritis during the disease, which can progress to renal failure [30]. In severe forms of renal impairment, the appearance of secondary hyperparathyroidism causes an increase in osteoclastic activity and bone resorption [29, 30]. Another mechanism may be a low level of 1.25 dihydroxy vitamin D by decreasing alpha1 hydroxylase activity in the kidney [59].

- Serological factors: Although autoantibodies role in influencing bone metabolism is unclear, anti-Ro may increase the osteoporosis risk [27, 31]. Up to date, no correlation between the presence of anti-dsDNA antibodies and bone mass has been demonstrated. The anti-Sm could have a protective role [31].

- Metabolic factors: Vitamin D deficiency in SLE can be determined by several factors such as photosensitivity, involving avoidance of sun exposure and use of SPF protection screen, kidney failure, disease activity, prolonged glucocorticoid therapy, the presence of anti-vitamin D antibodies (approx. 4 % of patients) [59].

- Hormonal factors: Unlike the general population at risk for osteoporosis, which has an estrogen deficiency (especially women over 50 years), in SLE, there is a predilection for females in the 15-45 age group, with high levels of estrogen. In those patients, low levels of androgen hormones appear to have a stronger influence on bone metabolism than relatively high levels of estrogen [32].

- Genetic factors: The density of bone structures could be influenced by the genetic polymorphisms of the vitamin D receptor - FOK I (FF, Ff, ff). However, a prospective study conducted during 5.3 years did not show a significant difference between the three genotypic groups [33].

The impact of medication on osteoporosis in SLE

Corticosteroid therapy influences in a dual way the bone mineral density in patients with SLE. On the one hand, its risk of inducing osteoporosis is well known, but it may also play a beneficial role by reducing systemic inflammation's effects on the bone. Two extensive prospective studies [29, 34] have shown that bone loss in SLE occurs predominantly in patients treated with at least 7.5 mg prednisone per day.

Hydroxychloroquine. The contribution of this treatment in osteoporosis prevention is not yet well defined. Despite this, the control of systemic inflammation with immunosuppressive drugs is important both by reducing inflammatory outbreaks and also by reducing the dose and duration of corticosteroid therapy. In women with SLE, HCQ use was associated with higher BMD in the lumbar spine [31, 61, 62] and hip [62]. However, more extensive studies are needed in patients with SLE and other rheumatic diseases in which hydroxychloroquine is used.

The risk of fracture in SLE

Fractures can be an important complication in the course of patients with SLE. The data accumulated in recent years demonstrates an increase of 1.2 - 4.7 times the risk of symptomatic fractures than the general population (Echblorn 2013). In the case of vertebral fractures, which can frequently be clinically inapparent, morphometric analysis is important. Morphometric identification of vertebral deformities is also significant for the attending physician because it is associated with significant impairment of quality of life and an increased risk of symptomatic fractures (e.g., hip) [35]. Current studies showed the presence of at least one vertebral fracture in 3.7-50% of patients with SLE [35, 36, 37-42].

The etiology of fractures is multifactorial in patients with SLE, including bone-dependent factors and factors associated with the risk of falling [36].

The main factors associated with the increased risk of symptomatic fractures in SLE are:

- Age;
- Menopause;
- Smoking, alcohol consumption;
- Duration of the disease;
- Kidney damage;
- Decreased BMD;
- Duration of treatment and cumulative dose of glucocorticoids.

In addition, patients with SLE have an increased risk of falling and associated conditions: physical asthenia, joint damage, neurological complications, impaired visual acuity or decreased muscle strength (which may be associated with both inactivity and corticosteroids or vitamin D deficiency) [8, 17].

A particular aspect of SLE patients is the relationship between bone mineral density and fracture risk. The idea of reduced BMD in patients with SLE is generally accepted, but not all studies showed a clear correlation with an increased risk of fracture. In addition, about 1/3 of patients with SLE and vertebral fractures have normal BMD [43, 44]. These data demonstrate the limited value of BMD in estimating fracture risk and the multifactorial etiology of SLE fractures.

PREVENTION AND TREATMENT OF OSTEOPOROSIS ASSOCIATED WITH SLE

SLE is a chronic condition that predominantly affects young women. Therapeutic regimens used to control the disease generally involve extensive and long-term use of glucocorticoids. Thus, decreased bone mineral density and increased fracture risk appear as natural problems in managing this condition. Lifestyle measures and control of risk factors are general principles in the management of osteoporosis and fracture risk. The current recommendations are based mainly on adopting a healthy lifestyle and preventing falls (as a central risk factor in fragility fractures).

Important aspects are: avoiding smoking, alcohol consumption, maintaining an optimal weight and regular physical activity. From a nutritional point of view, the measures are based on optimizing the intake of calcium, proteins and vitamin D, essential for bone mineralization and maintaining an adequate neuromuscular function. Data from the literature recommend a daily calcium intake of at least 1000 mg (1200-1500 mg in patients with corticosteroids), the dosage of serum level and supplementation with 800-1000 IU vitamin D per day and a protein intake of 1 g/kg per day [45].

Pharmacological therapy in SLE is addressed primarily to osteoporosis patients with a history of fragility fracture and glucocorticoid treatment.

The 2010 American College of Rheumatology (ACR) recommendations for preventing and treatment of glucocorticoid-induced osteoporosis include bisphosphonates as the first-line medication for postmenopausal women and corticosteroid patients [45]. This therapeutic class presents consistent evidence of efficacy in increasing BMD and reducing the risk of fracture. The antiresorptive agents inhibit bone resorption by attaching to the active remodeling sites causing apoptosis of osteoclast cells. The main representatives of the class currently used are the second generation drugs (e.g., alendronate, ibandronate, pamidronate) as well as those of the third generation, with much higher potency (e.g., risedronate and zoledronic acid). They are recommended for patients with normal renal function [45] to prevent and treat glucocorticoid-induced osteoporosis. Limited data on the teratogenic effects of bisphosphonates require their administration only to postmenopausal women [46]. In addition, patients should be informed of the risk of complications such as osteonecrosis of the jaw or atypical femoral shaft fractures, especially in patients on corticosteroid therapy [47-49].

Studies have identified new therapeutic targets in osteoporosis, such as cathepsin K, sclerostin, or the RANKL system. Of these, denosumab, an anti-RANKL monoclonal antibody, has entered and prevailed in clinical practice being an option for premenopausal women with glucocorticoid-induced osteoporosis, as well as for patients with SLE and renal impairment [27].

The risk of osteonecrosis of the jaw and atypical fractures remains in this category of therapeutic agents. Potential complications are the rebound fractures phenomenon and the greater tendency towards hypocalcemia [60].

Estrogen replacement therapy to prevent osteoporosis in patients with SLE is not recommended, as it is associated with an increased rate of inflammatory flares and thromboembolic events [50]. Raloxifene, a selective modulator of estrogen receptors, is an option for postmenopausal women with inactive lupus and without a history of thrombotic events or antiphospholipid antibodies [51].

Another treatment, the recombinant human PTH analogs (e.g., teriparatide), may be an option for men and postmenopausal women who have not responded to bisphosphonate therapy and are at increased risk of fracture [53]. The experience in the young adult population, including premenopausal women, is limited, so this treatment should be initiated only when the benefits outweigh the risks. Premenopausal women with glucocorticoid-induced osteoporosis should be considered at high risk of fracture if they have a pre-existing fracture or a combination of risk factors such as low bone mineral density, intensive treatment with glucocorticoids in high doses (≥7.5 mg/day) for at least six months or background disease in acute onset [52]. In patients with glucocorticoid-induced osteoporosis, this drug was associated with an increased BMD and a significant reduction of vertebral and non-vertebral fractures, but not of hip fractures, compared to the group treated with bisphosphonates [53, 52]. The administration must be made with caution in patients with moderate renal impairment [54].

SCREENING AND MONITORING OF TREATMENT

Patients should be monitored during the therapy by periodic reassessments, both biologically (alkaline phosphatase, blood calcium levels, phosphatemia, urine calcium levels, etc.) and imaging (bone densitometry, skeletal radiographs to document fractures). The inadequate response, low adherence, or adverse reactions to treatment, call into question the decision to discontinue or change it [55, 56].

Regarding the direct assessment of fracture risk, we mention that there is no current algorithm accepted and adapted to patients with SLE. The most widely used in practice is the Fracture Risk Assessment (FRAX), proposed by the World Health Organization [55]. FRAX has important limitations in SLE: it was developed for the postmenopausal period (and thus does not cover a significant subgroup of patients), does not take into account the cumulative dose of glucocorticoids (but only their use or not), and does not include fall risk assessment and the presence of vertebral deformities [27].

CONCLUSIONS

The last decades have made significant progress in the evaluation and treatment of patients with SLE, allowing current therapeutic strategies to control and stabilize affected organs. In this context, associated osteoporosis and fracture risk have become important in the medium and long term management of the disease.

At the moment, the practitioner has consistent data on the epidemiology, pathogenic mechanisms, and clinical impact of osteoporosis and fractures in patients with SLE. Current recommendations include: optimizing calcium and vitamin D intake, lifestyle adjustments and drug treatment. Special attention is directed to the group of women at fertile age, for whom treatment options are still limited.

Additional data on screening methodology and algorithms, morphometric assessment and fall risk are expected. In spite of this, there are currently several arguments for rheumatologists in order to turn their attention to the management of these complications from the early stages of the disease.

Ovarian cancer under the magnifying glass

Ionut M. Cobec[1], Roxana Popescu[2], Aurica E. Moatar[3,4], Doina Verdes[2]

Abstract: *Cancer is a pathology generating problem to the public health systems all over the world.*

The etiology and pathogenesis of ovarian cancer are still partially unknown. It is still a challenge when it comes to the origin, the molecular basis of ovarian carcinogenesis, tumor progression, and therapy options of ovarian cancer.

This paper brings an overview of ovarian cancer, starting with the pathogenesis, histopathological forms, and molecular biology of ovarian cancer, and follows the growth factors as molecular targets for specific therapy.

Keywords: *ovarian cancer, pathogenesis, molecular biology, growth factors*

INTRODUCTION

Ovarian cancer is a pathology that throughout history has sparked both controversy and questions, some of which remain unanswered to this day. Over time we have been working hard towards laying the foundation for the current therapeutic standard in addressing existing ovarian tumors.

Following the epidemiological data and the steps taken gradually by our forerunners in their pioneering work in both surgical as well as drug therapy, but also the new findings in the field and the literature developed, overall representing a rich scientific dowry, we realize that we are faced with pathology that over time rose many difficulties for clinicians, researchers, and patients under therapy.

EPIDEMIOLOGY AND PATHOGENESIS DATA

Cancer is a pathology generating problem to the public health systems in Romania, its incidence being among the lowest in Central and South-East Europe, whilst having a higher mortality rate [1]. Both body functions and immune response are involved in the pathogenesis of cancer and angiogenesis, hypoxia and inflammation can be identified at the cellular level [2].

The etiology and pathogenesis of ovarian cancer are still partially unknown [3, 4].

When determining the origin of ovarian cancer, there are several theories including the theory of the de novo ovarian cancer [5], the hypothesis of the inclusion of cysts [6, 7, 8] based on a Mullerian phenotype causing the malignant transformation of the mesothelial ovarian cortex corresponding to the serous, endometroid, mucinous, clear cell, transition types, but also to the Mullerian epithelium found outside the uterus, fallopian tube, cervix [7, 8, 9, 10, 11]. The fallopian tube may be more or less involved in the origin of serous ovarian cancer, both through the proliferation of fallopian secretion cells and through its vicinity, causing dysplastic lesions, the inclusion cysts formed at the time of ovulation near the fimbria causing the

formation of endosalpingiosis [6, 12, 13], the transformation of epithelial ovarian inclusions, of the serous adenomatous cyst into an ovarian borderline serous tumor which may become invasive carcinoma [14, 15, 16].

PECULIARITIES OF HISTOPATHOLOGICAL FORMS OF OVARIAN CANCER

Ovarian cancer has the following histological types according to WHO (World Health Organization): serous, endometrioid, mucinous (most common), clear cell, transitional cell, squamous cell, and undifferentiated and mixed epithelial. Tumors can be benign, malignant, or borderline, and, depending on the subtype, they can be low grade or high grade (depending on nuclear atypia and mitosis) [17, 18]. Borderline tumors are considered potentially indolent and weakly malignant [19, 20, 21].

Ovarian cancer can be classified as follows: type I consisting of low-grade carcinomas -serous, endometrioid, clear cell, mucinous, and Brenner tumors, they are generally indolent, may have originated in borderline tumors and endometriosis, showing molecular entities such as KRAS, BRAF, ERBB2, PTEN, CTNNB1, PIK3CA, and type II consisting of high-grade carcinomas, serous, endometrioid, mixed mesodermal malignant tumors (carcinosarcomas) and undifferentiated carcinomas, they are generally aggressive, characterized by genetic instability, may have originated in intraepithelial carcinoma of the uterine tube, their molecular entity presented as mutations at the TP53 level [19, 20, 21, 22, 23, 24]. Both types may have originated in the extra ovarian tissue that can be implanted in the ovary [25].

Following the changes made in the FIGO staging, a new staging resulted. As recommended by FIGO, it is indicated that histology, including the grading, should be part of the staging process and also that the primary site (ovary, fallopian tube, peritoneum) should be mentioned where possible, and if this is not possible, this also must be mentioned. The damage to the retroperitoneal lymph nodes must be proven histologically or cytologically and stage I tumors with dense adhesions can be classified as stage II if malignant cells are proven to be histologically present [6, 26]. According to the International Agency for Research on Cancer (IARC), from histology's point of view, we can differentiate between carcinomas (serous carcinomas, mucinous carcinomas endometrioid carcinomas, clear cell carcinoma, NOS adenocarcinoma, other specific carcinomas, nonspecific carcinomas), sex-cord stromal tumors, germ cells tumors, other specific cancers (these including malignant Brenner tumors, carcinosarcomas, mixed Mullerian tumors), non-specific cancers [27, 28].

MOLECULAR BIOLOGY OF OVARIAN CANCER

The molecular basis of ovarian carcinogenesis and progression are not yet fully elucidated, considering the genetic and epigenetic alterations that translate into alterations of the molecular signaling pathways involved in survival, proliferation and cell death, adhesion, and angiogenesis.

Carcinogenesis involves inadequate adjustment mechanisms of the signaling pathways governing cell cycle, differentiation, apoptosis, expression of oncogenes and/or antioncogens, the action of transcription, and growth factors [29, 30, 31].

Amongst the RB family members, the RB gene (retinoblastoma gene) is involved in ovarian carcinogenesis. The majority of malignant ovarian tumors have had a strong expression of the pRb about a normal ovary where the protein is barely detectable [32, 33]. It was demonstrated that overall survival was positively influenced by the positive expression of p21 and p27 in patients with negative p53 only [34]. The p53 is the most relevant oncosupressor gene. Inactivation of the p53 oncosupressor gene's function appears to be an early event in hereditary ovarian cancer induction characterized by germ mutations of the BRCA1 tumor suppressor gene. The somatic mutation of p53 is the most common molecular change that occurs in epithelial ovarian cancer. The immune-histochemical expression of p53 protein was associated with the highly differentiated serous type, positive cytology, residual tumor, and stage of disease [4, 35, 36, 37, 38].

Studies in the specific literature suggest that the expression of Bcl-2 and Bax is an important prognostic marker [39].

The ovary is subject to cyclical changes where the angiogenesis process is continuous [3]. VEGF (vascular endothelial growth factor) is a growth factor that stimulates the angiogenesis process and increases microvascular permeability [40]. Ovarian cancer causes the release of VEGF in response to conditions of hypoxia and acidity, the serum and ascitic fluid VEGF values being elevated with malignant tumors as opposed to benign [40, 41, 42 43]. Type I and II ovarian tumors differ in molecular-genetic evidence just as much as they differ morphologically [44].

High-grade serous ovarian cancer, which is part of type II tumors, has frequently known mutations of TP53 (in more than 80% of cases) and amplification of CCNE1, which are characteristic of type II tumors, but rarely mutations that characterize type I tumors such as KRAS, BRAF, ERBB2, PTEN, CTNNB1 and PIK3CA [44, 45, 46, 47]. Type I tumors are more stable genetically and show distinctive pattern mutations that happen in a particular cell type, as opposed to type II which present morphological and molecular homogeneity, are genetically unstable with a high-frequency mutation of TP53, thus suggesting that ovarian tumors develop on different molecular pathways [44, 48]. The mutations in the KRAS or BRAF lead to subsequent activation of the MAPK signaling pathway (mitogen-activated protein-kinase) [49, 50]. It was shown that some inflammatory markers, glucose protein transporter 1 (Glut-1), iNOS, cyclooxygenase-1 (COX-1), cyclooxygenase-2 (COX-2), nuclear factor kappa B (NF-kB) are involved in the initiation and progression of cancer [51, 52]. Immunohistochemical analyses showed statistically increased levels of expression of Glut-1, iNOS, COX-1, COX-2 in type II ovarian tumors, but no statistical difference of expression of NF-kB in ovarian tumors type I and II [52].

Researchers have identified five molecular subtypes presenting clinicopathological characteristics and survival rates for ovarian epithelial cancer, which are: Epi-A, Epi-B, Mes and Stem-A, and Stem-B. Epi-B and Stem-A subtypes are independent prognosis factors [53].

The BRCA1 gene was often studied because of the proven implications in the transmission of hereditary breast and ovarian cancer. In molecular terms, we distinguish as follows: low-grade serous ovarian carcinoma presents KRAS and BRAF mutations, and the high-grade present mutations of TP53 and abnormalities of BRCA. Serous high-grade ovarian carcinoma shows an increased nuclear expression of Ki-67 and has immunoreactions for p53, BRCA1, WT1, p16. Mucinous ovarian carcinoma presents KRAS mutations in its tumorigenesis, which are immunoreactive for CK7 and CK20. Endometrioid ovarian carcinoma shows mutations of the β-catenin (CTNNB1), PTEN, and ARID1A. Endometrioid ovarian carcinoma is immunoreactive for vimentin, CK7, CK20, the epithelial membrane antigen, estrogen, and progesterone receptors. Ovarian clear cell carcinoma presents ARID1A mutations, lack of protein BAF250, is positive for HNF1-β, and is negative for ER and WT1 [5, 54, 55, 56, 57, 58].

GROWTH FACTORS AS MOLECULAR TARGETS FOR SPECIFIC THERAPY

Knowing that VEGF is involved in tumor growth, invasion, and dissemination to the lymph nodes, liver, lungs, numerous drug agents are being used with the target role occupied by VEGF in ovarian cancer, especially when peritoneal carcinomatosis and/or ascites are present. One of the agents used in neutralizing the VEGF is bevacizumab, a recombinant humanized monoclonal antibody that stops the binding of VEGFRs on all the VEGF isoforms, thus preventing tumor growth and ascites production. Paclitaxel can be used in combination with bevacizumab acting synergistically and with the same effects. Bevacizumab used in combination with cisplatin increases the survival rate [59, 60, 61].

Agents acting as inhibitors of tyrosine kinase receptors are counted as VEGFR antagonists (Ramucirumab, Cediranib, Semaxanib) and agents that have as target multiple tyrosine kinase receptors (Sunitinib, Sorafenib, Vatalanib, Intedanib, Pazopanib, Motesanib, Vandetanib, AEE788) [62, 63].

VEGF overexpression in ovarian cancer makes it a therapeutic target, thus aiming at the inhibition of neo-vascularization, but also anti-angiogenic agents. VEGF is a dimeric protein, a member of the VEGF/PDGF, including VEGF-B, VEGF-C, VEGF-D, PIGF, and PDGF, involved in angiogenesis, proliferation, survival, migration of endothelial cells and stimulated by hypoxic conditions [12, 60, 64, 65].

Anti-VEGF therapy has been shown to play an important role in female patients with primary and recurrent ovarian cancer [60, 61, 66]. The use of bevacizumab can have aggressive complications that can lead to death, the risk is even higher when used in combination with chemotherapy, particularly platinum-based (cisplatin, carboplatin, oxaliplatin) or taxanes (paclitaxel, docetaxel) [66, 67, 68, 69]. As standard therapy in advanced ovarian cancer, cytoreduction surgery followed by platinum-based chemotherapy is used with a fairly good response, but sometimes resulting in tumor recurrence within 5 years and therapeutic resistance [66]. In case of resistance to platinum other chemotherapeutics are used such as metronomic paclitaxel, docetaxel, topotecan, liposomal doxorubicin, etoposide, gemcitabine, but the response is quite limited with a fairly low survival rate [50]. Attempts have been made to develop different therapies aiming at the interruption of angiogenesis, molecular target, inhibition of the Poly- (ADP) Ribose polymerase function (PARP), growth factors such as insulin-like growth factor (IGF) [70, 71]. Treatments often target the vascular endothelial growth factor pathway (using bevacizumab or aflibercept), the mechanisms of DNA repair (using iniparib or olaparib), or are guided against folate ways (using pemetrexed farletuzumab, vintafolid) [61].

Oral therapy with olaparib is currently being used as maintenance therapy, this being a PARP inhibitor used on patients with recurrent serous ovarian cancer sensitive to the platinum-based therapy, where the existence of mutations in BRCA has been proven and where the patient had two or more courses of platinum-based chemotherapy and showed a partial or complete response to the most recently used platinum-based chemotherapy [22, 71, 72, 73, 74, 75, 76].

ORIGINAL ARTICLES

Overview of bilirubin as criterion for higher military education admission

ViorelM. Oniciuc[1]

Abstract: *This article was written because of the necessity of clarifying the recent biomedical selection criterion for the medical exam of the students who are applying for higher military education. In order to screen for or monitor liver disorders or hemolytic anemia the bilirubin is measured. The increased values of the bilirubin can be caused by multiple factors and they are presented in the following chapters.*

Keywords: *Bilirubin, liver, gall, alimentation, genetic diseases*

WHAT IS BILIRUBIN?

Bilirubin is a linear liposoluble tetrapyrrole derived from the enzymatic catabolism of the hem fraction from various hemoproteins in the body. Understanding changes in plasma levels of bilirubin under pathological conditions and differentiation of icteric syndromes involves a prior knowledge of the mechanism of formation, agglutination and elimination of this compound.

The normal values observed in the laboratory analysis are:
- Total bilirubin = 0.3 - 1.2 mg / dl, (or 0.1 - 1.2 mg / dl)
- Direct bilirubin = 0.1 - 0.35 mg / dl
- Indirect bilirubin = difference

Linear tetrapyrrole is the result of the enzymatic mechanism that catalysis the oxidative breakdown of the tetrapirolic (porphyrinic) ring of the hemoglobin heme molecule, primarily of the aged erythrocytes.

The process leads to hemoglobin formation in at least two stages. Bilirubin is mainly formed in the liver (about 80-85% up to 90% according to some authors), the rest having extrahepatic origin, in part reticuloendothelial (spleen, bone marrow).

Involvement of the liver in bilirubin production

The main degradation product of porphyrins is bilirubin, the red-orange bile pigment, which still possesses the four pyrrole rings. In the plasma, the pigment circulates as total bilirubin, consisting of two components: bilirubin bound to unconjugated albumin, indirectly referred to as free glucuronide bilirubin (mono- and diglucuronate), related to the diazotation reaction, Hijmans Van Den Bergh. Total bilirubin level serum concentration is 0.1-1.2 mg/dL or 17 μmol/l. Under normal circumstances, bilirubin accounts for 85% of the erythrocyte hemoglobin degradation and the remaining 15% originates in the degradation of other hemproteins such as myoglobin, cytochromes and other hemic enzymes (catalases, peroxidases, cytochrom-oxidases).

Direct bilirubin (agglutinated with glucuronic acid) circulates freely in the blood. Indirect bilirubin (primary, unconjugated) is transported by binding to albumin, partially in the form of the albumin-phosphatide complex and in small amounts bound to both metals, amino acids, peptides or other small molecules. In the gall there are bilirubin esters with sulfuric

acid and other acids. By binding the bilirubin to the elastic fibers of the skin and the conjunctiva the symptoms of jaundice appear (yellowing of the skin and conjunctiva).

Bilirubin production is 35 mg per gram of hemoglobin, yielding 250-300 mg daily bilirubin. Hemoglobin degradation in bilirubin is performed in Kupffer stellate cells in the hepatic reticulo-histocithic system (RHS), which is the primary location of the process, the spleen and bone marrow being organs involved in this activity.

The secretion of the gall

One of the most important functions of the liver is the production of its external secretion, the gall, which reaches the duodenum through the biliary tract. The gall fulfills two major functions:

• elimination of endogenous substances – end products of metabolism and foreign substances such as bromsulfonaphthalein (BSP) drugs and dyes;

•intervention in lipid digestion and reabsorption – the liver secreted by hepatocytes, the hepatic ball, differs in appearance and concentration of vesicular bile. The first one is clear, yellow-gold and almost isotonic with blood, and the second is of brownish green (oxidized bilirubin), cloudy and filthy. Vesicular vesicle is more concentrated than the liver due to water reabsorption through the bladder wall.

INCREASE IN BILIRUBIN VALUES

Without entering into anatomical and physiological details and the claim of accurately discovering the causes that cause the increase of bilirubin values, applying filters such as the elimination of neo-natal casuistry, serious diseases (cancerous disease, cirrhosis etc), which have a very low incidence at the age of the students, we can focus on two main directions that could underpin the rise of increased bilirubin at our students:
1. Physiological-behavioural and social.
2. Inherited, triggering some hereditary disease syndromes.

Prior to the two directions, two further specifications are required:
• The triggering of the studied phenomenon belongs mainly to the age of adolescent-premature.
• In specialty work, the possibility of recording normal values occurs once in 3-5 laboratory tests, at intervals of at least three weeks, repeated bilirubin tests can be associated with other investigations, to determine normal hepatic functionality.

1. On the liver tract, intrahepatic and extrahepatic, gall bladder, biliary bladder, we narrowed down the multitude of possibilities with pathological manifestation (even anicteric, cholestasis mild hepatitis, confirmed by Dr. Anton).

However, it is worth mentioning that hyperbilirubinemia has been reported in a different institution, namely the "Football Academy" (according to A. Constantinescu – Fundeni University Clinic)

We noticed an increase of bilirubin in the cases of:
• Automedication (we advise that medication is administered and supervised by the medic):
- Paracetamol, even a slightly increased dose,
- Oral contraceptives,
- Consumption of food supliments, protein for muscle mass.
- Energy drinks, sweet juices, fast food
• Alimentation (canteen, home or other sources):
- Lack of food diversity
- Lack of lipids in the diet

The most important aspects of nutrition belong to food adjuvants mainly preservatives:
- Sodium metabisulphite (E223) in biscuits, cakes, fast food, juices, pickles, medications.
- Monosodium glutamate (called "good taste") is less directly incriminating, but it induces fatigue, headaches, sometimes aggravating breathing, causing stress. It is omnipresent in soups, sausages, vegetable preserves, flavors etc. This heat-treated (E621) adjuvant gives the browning reaction resulting in very toxic compounds.
- Sodium benzoate, preservative (E211).
- Carbon tetrachloride, hepatotoxic.

An important factor is "pernicious anemia" - ineffective erythropoiesis, lack of vitamin B12 due to lack of food, or more severe, due to the lack of intrinsic Castle's factor in gastric juice, necessary for absorption. B12 or perhaps stress-related somatostatin secretion that inhibits the secretion of the Castle's factor.

Sure, the theme is vast. Surveillance over time and complementing with specific analyzes, not just laboratory (CT, eco) will explain the causes.

2. On the track from the liver, intra-, extracapsal, bile duct to gall bladder several hereditary transmission syndromes can be manifested with precise localization and with a slightly variable pathological manifestation. They are triggered at adolescent age, according to the algorithm for the interpretation of the functional - liver test results (according to Henry J.B.). The most common genetic diseases are:

- *The Gilbert syndrome*

It is characterized by chronic, benign, intermittent, familial hyperbilirubinemia found in a routine control. It is caused by a defect in the transport and conjugation of unconjugated bilirubin. The jaundice is accentuated in feverish states, physical exertion or consumption of oral contraceptives.

- *The Crigler-Najjar syndrome*

Type I may be a homozygous of Gilbert's disease. Type II is characterized by partial glucuronide-transferase deficiency that bilirubin conjugates to the liver cell. Usually at adolescents, complications are rare and occur in the case of poor eating habits or by excluding lipids from the diet.

- *The Dubin- Johnson syndrome*

It is characterized by the inability to transport bilirubinuriuronide from hepatic cells to the tubule while the conjugation is normal. The stress periods are a factor. The jaundice is harmless and reversible and occurs after eating estrogen and contraceptives. It can be confused with mild viral hepatitis.

- *The Rotor Syndrome*

It is asymptomatic, benign; withdrawal and storage of conjugated bilirubin defect, and possibly related to transfer from liver to bile. Usually it is reported in adolescents (medication, exercise-physical stress). Other liver functions are normal.

- *Epstein-Barr virus infections (human herpesvirus 4)*

It induces bilirubin increases in about 30% of the patients, but if liver function abnormalities are not found, another diagnosis should be sought.

CONCLUSIONS

After analyzing the studied material together with the medical laboratory specialists (Chem. Stanciulescu C., Synevo, Biochem. Apircioaei O., former SMC), the two physicians mentioned above, Dr. Stanciulescu P., internal specialist and I tried to highlight some aspects of hyperbilirubinemia:

- Self-medication - forbidden.
- Nutrition - the main recommendations:
  - Regular fresh fruits and vegetables consumption
  - Reduced fast food and unhealthy drinks consumption.
  - Reducing fast at the first deviations from the normal functioning of the body, especially during the body-growing period.
- Elimination, at least limitation of stress, in all forms of manifestation: physical, food, intellectual, psychosocial.
- Avoid fatigue of any kind (not enough sleep at night)

These landmarks must be all considered, taking care of only one recommendation cannot bring immediate positive results.

As for hereditary transmission diseases, unfortunately, the possibilities of reaction are very limited in Gilbert and Crigler - Najjar syndromes, phenobarbital brings a certain decrease (Jacques Wallach, p. 341, confirmed by Dr. Anton) only under the supervision of the doctor. The most important factor is however a varied diet, avoiding starvation and tiredness.

Overview of telemedicine use aspects in natural and technical disaster and combat situation

Hamid R. Rasouli[1], Karim S. Kondor[2], Fathollah Ahmadpour[1], Mohammad Nobakht[2], Ali A. Esfahani[2], Mohsen A. Farajzadeh[2]

Abstract: *Background: Preparation and hospital development estimated an essential part of the policies and strategic purposes of healthcare in each government. Today, applications of management to reduce the burden of natural and technical disasters appear are very necessary.*

Objectives: The study aimed to review the major relevant articles in the case of the application of telemedicine for trauma injuries in disaster and military situations.

Methods: Original clinical trials investigating the effects of telemedicine on trauma injuries published before April 2018 were aggregated, and used in this study. We search the scientific sources such as PubMed, MEDLINE, Wiley, EMBASE, ISI, and Scopus. The keywords that applied to identify these articles combined: Telemedicine, Mobile Health, Health, Mobile, mHealth, Telehealth, eHealth, Trauma, War, military, medicine, Wounds and Injuries, injuries.

Results: The text of the articles and abstracts were examined from various aspects, the 21 articles were evaluated for quality, and then 10 papers entered in a systematic review. We found that the use of telemedicine in trauma injury, rural and the military is very helpful for high-quality trauma care; also the telemedicine and telephone consultations can be were demonstrated reducing the risk of physician-related medicine mistakes. The economic evaluation of telemedicine was demonstrated cost-saving and cost-effective of telemedicine consultations. We also realized the importance and practicable of telemedicine for improving rural trauma care.

Conclusions: Ultimately, the telemedicine can help patients and health government organizations economically, the telemedicine consultations due to cost-saving and cost-effective. Further studies to evaluate the running of telemedicine need to abating the practical and high-efficiency method, that can be done everywhere and it's free from mistakes and defects.

Keywords: *telemedicine, trauma, disaster*

BACKGROUND

Preparation and hospital development estimated an essential part of the policies and strategic purposes of healthcare in each government. Today, applications of management to reduce the burden of natural and technical

[2] Marine Medicine Research Center, Baqiyatallah University of Medical Sciences, Tehran, Iran

disasters appear are very necessary. [1, 2]. Telemedical technology is increasingly moving into the medical system. Teleconsultation between crisis positions with a lack of specialists' physician and a trauma center in surgical and trauma patients could save interventions [3-5]. In recent years, Telemedicine is growing more prevalent in intensive care medicine, but its impacts and the excellent organizational pattern is also ambiguous [6-8]. Particularly in situations that there is a shortage of extremely educated healthcare workers on-scene such as rural EMS, disaster, and military conditions, conditions teleconsultation could improvements in patient care via consultation of a specialist [3-7].

Telemedicine is a valuable method of implementing remote diagnoses such as ophthalmology, dermatology, and radiology [8]. Telemedicine represents the use of medical knowledge transferred from one position to another by electronic connections to enhance patients' health situation and care [2-5]. Crisis management in natural and technical disasters should decrease the harmful impacts of trauma events, mortality, and morbidity applying a designed program of development and mobilization. Notwithstanding, there are a lot of experiences in crisis management, it has limited application of telemedicine in disaster and military situations [2-6].

Application of the telemedicine in disaster and military situations management is the principal subject to maintain the health of accident patients [7]. Regarding the destruction created in the health services infrastructure, infrastructure has become a significant issue, the existence, and utilization of telemedicine technology and according to continuous development in electronic technology, communication to deliver health services in remote regions [6-8].

We try to review the major relevant articles in case of application of telemedicine for trauma injuries in disaster and military situations to help clinicians and patients to have a better understanding of these technologies and choosing the better therapeutic option. A highly standardized evidence-based review can be one of the best references for clinicians to decide about their treatment plan.

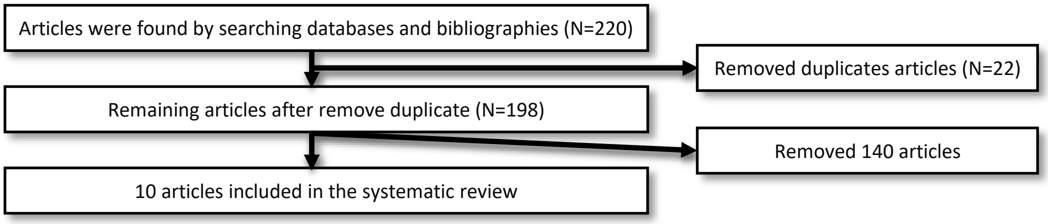
MATERIALS AND METHODS

Original clinical trials investigating the effects of telemedicine on trauma injuries published before April 2018 were aggregated, and used in this study. We search the scientific sources such as PubMed, MEDLINE, Wiley, EMBASE, ISI Web of Knowledge, and Scopus.

The keywords that applied to identify these articles combined: Telemedicine, Mobile Health, Health, Mobile, mHealth, Telehealth, eHealth, Trauma, War, military, medicine, Wounds and Injuries, injuries. Two authors have independently assessed the titles and abstracts of all papers obtained by the searching method outlined above.

The studies with the following criteria were excluded: did not evaluate the performance of Telemedicine; were not English-language study, and were review studies and letters to editors or conference abstracts. The two reviewers who carried out the literature search also individually made decisions and selected studies considering inclusion criteria. The following details were extracted from included studies independently by two reviewers, study location, year of publication, the first author's surname, study design, and outcomes.

Figure 1: Flow chart the inclusion studies



Articles were found by searching databases and bibliographies (N=220)
Removed duplicates articles (N=22)
Remaining articles after remove duplicate (N=198)
Removed 140 articles
10 articles included in the systematic review

RESULTS

Ten studies matched the criteria for analysis and discussion.

Daniel et al. (2013) in a randomized trial study examined emergency care between two groups. Doctor-staffed EMS teams compare to paramedic teams that were established telemedical by an EMS doctor. Overall 16 teams that each team contained one EMS physician and two paramedics randomly divided into the control and telemedicine group. Telemedical functionalities included 2 methods of audio communication, transportation of vital information, and video streaming from the situation place to the remotely placed EMS doctor. There were no significant differences in the case-specific items and, no potentially hazardous mistreatments were reported. They showed telemedical supported paramedic care as possible and at least not poor respect to conventional EMS teams with a doctor on-scene in these situations [9].

Table 1: Author's name, type of study and summaries of outcomes in the studies

Author's name	Type of study	Outcomes
Daniel et al. (2013) [9]	Randomized trial study	They showed telemedical supported paramedic care as possible and at least not poor respect to conventional EMS teams with a doctor on-scene in these situations
Brennan et al. (1998) [10]	Randomized trial study	They concluded that telemedicine was observed to be a satisfying system for pre-chosen emergency department patients and was observed by the doctors as an admissible way of complementary application.
Bowman et al. 2003 [11]	Cross-Sectional	Their results showed Telemedicine was a precise, reliable, and effective way of diagnosing and controlling these patients, particularly if slit-lamp images were applied.
Yang et al. 2015 [12]	Cross-Sectional	They concluded that a healthcare payer aspect, telemedicine to health care workers of severely sick and pediatric patients performing to rural EDs are cost-saving or cost-effective regarding the telephone.
Mohr et al. 2016 [13]	Observational cohort study	The telemedicine consultation was requested for severely injured rural traumatic patients (burns, penetrating trauma, and those with abnormal vital signs) in the Emergency Department, but Telemedicine consultation was not decreased interhospital transfer.
Oeveren et al. 2017 [14]	Cross-Sectional	They demonstrated a success rate of 96% of telemedicine during emergency intubation. Telemedicine-assisted intubation can be performed in rural hospitals practically.
Gilmore et al. 2014 [15]	Cross-Sectional	HBT can provide mental health services in a preferable procedure of location in military sexual trauma with PTSD patients and help to them for reducing mental pains and increasing readiness.
Dayal et al. 2016 [16]	Retrospective cohort study	The performance of a telemedicine program is designed to assist in the seriously ill children at admission to the PICU. They provided evidence for improving clinical outcomes in pediatric critical care with telemedicine programs.
Shah et al. 2016 [17]	Prospective cohort study	High-intensity telemedicine can be alternative to traditional severe disease care and it must be included in population health programs.
Dharmar et al. 2018 [18]	Retrospective chart reviews	They were demonstrated reducing the risk of physician-related medicine mistakes among critically sick and traumatic children of 8 rural EDs from academic children's hospital.

Brennan et al. (1998) conducted a randomized clinical study in the emergency department. Overall 104 patients were included. Fifty-four participated in the telemedicine group and 50 to the control group. There are no differences between the groups for an incident of 72 hours emergency department return visits; the requirement for further care; doctor communication; nurse communication; satisfaction. The mean patient throughput period for the telemedicine group was 106 minutes; the mean for the control group was 117 minutes. They concluded that telemedicine was observed to be a satisfying system for pre-chosen emergency department patients and was observed by the doctors as an admissible way of complementary application [10].

Bowman et al. (2003) assessed the precision and effectiveness of telemedicine in diagnosing and treating eye injuries. The methods were a clinical trial with a face-to-face group (40 patients) and a telemedicine group (40 patients). In the face-to-face group, consultations were in person; in the telemedicine group, researcher one handled video conferencing technology at 384 kbit/s, and observer two observed the patient face to face. In this study, 80 patients were included in the department. Principal result measures were agreement levels between the two observers for every phase, time of consultation, and several unnecessary recalls. There were more important conflicts applying telemedicine, in per sample the telemedicine diagnosis and management failed on the side of safety; consequently, no patient would have experienced via the improper administration because of the consultation using telemedicine. Their results showed Telemedicine was a precise, reliable, and effective way of diagnosing and controlling these patients, particularly if slit-lamp images were applied [11].

Yang et al. (2015) carried a financial assessment to determine the price, effect, and return on investment of telemedicine consultations presented to health care workers of severely sick and pediatric patients in rural EDs confronted with phone consultations from a healthcare payer prospect. The cost-effectiveness investigation was according to program effectiveness, obtained from change choices after telemedicine and telephone consultations. They concluded that a healthcare payer aspect, telemedicine to health care workers of severely sick and pediatric patients performing to rural EDs are cost-saving or cost-effective regarding telephone [12].

Nicholas M. Mohr et al. evaluated factors associated with telemedicine and interhospital transfer as a cohort study of all adult treated traumatic patients between 2008 and 2014 in North Dakota critical-access hospital (CAH). They demonstrated telemedicine consultation was requested for severely injured rural traumatic patients (burns, penetrating trauma, and those with abnormal vital signs) in the Emergency Department, but Telemedicine consultation was not decreased interhospital transfer [13].

Lucas Van Oeveren et al. evaluated intubations which done by telemedicine in rural EDs with ED telemedicine network. They were collected probable data of all patients with video telemedicine-assisted intubation from May 1, 2014, to April 30, 2015, and telemedicine involvement/intervention was evaluated using statistical analysis. Lucas Van Oeveren et al have involved 206 intubations with respiratory failure as most common. They demonstrated a success rate of 96% of telemedicine during emergency intubation. Telemedicine-assisted intubation can be performed in rural hospitals practically. This telemedicine-assisted intubation was done at first in emergency tracheal intubations via a live telemedicine link [14].

Amanda K. Gilmore et al. was described a randomized controlled trial comparing Prolonged Exposure (PE) delivered face-to-face and delivered via Home-based telemedicine (HBT) in female veterans, they focused on female veterans with military sexual trauma with PTSD. Their hypothesize was more be effective in improving the quality of life in PE delivered via HBT than SD at the post, 3-, and 6-month follow-up. Ultimately, Amanda K. Gilmore et al concluded HBT can provide mental health services in a preferable procedure of location in military sexual trauma with PTSD patients and help to them for reducing mental pains and increasing readiness. Generally, Home-based telemedicine can reduce systemic barriers for treatment [15].

Parul Dayal et al have compared the effects of access to a telemedicine program (pediatric critical care) on the intensity of disease and results for referral children to children's hospital PICU in the cohort study. The 582 patients with telemedicine that were younger and less sick than 524 patients from without telemedicine were compared during the study period. Parul Dayal et al was indicated the performance of a telemedicine plan for the care of seriously ill children. The performance of a telemedicine program is designed to assist in the seriously ill children at admission to the PICU. They provided evidence for improving clinical outcomes in pediatric critical care with telemedicine programs [16].

Manish N. Shah et al have evaluated the effect High-intensity telemedicine programs on emergency department use for the care of Six senior living community (SLC) residents in a cohort study over 3.5 years. They were indicated reducing emergency department use in High-intensity telemedicine care of SLC residents. Manish N. Shah et al was presented High-intensity telemedicine can be alternative to traditional severe disease care and it must be included in population health programs [17].

Madan Dharmar et al was evaluated the rate of physician-related medicine mistake on seriously 234 patients receiving 85 telephone consultations, 73 telemedicine consultation, and 76 no consultations in rural emergency departments, then outcomes of the study were compared. They were performed retrospective reviews critically sick and traumatic children of 8 rural EDs from academic children's hospital. Ultimately, Madan Dharmar et al was demonstrated reducing the risk of physician-related medicine mistakes among critically sick and traumatic children of 8 rural EDs from academic children's hospitals [18].

DISCUSSION

Traumatic injury is a common cause of death for those under the age of 44 years. On the other hand, accessing sufficient and adequate high-quality trauma care is a secondary problem after the trauma, and one of the main mechanisms associated with bad results in trauma patients. Generally, the improvement of trauma results is under the influence of triage of seriously traumatic patients. Telemedicine is a strategy to improve trauma care, with the aim of given tertiary level services locally. Using telemedicine is particularly increasing and improving the care of trauma patients, it can be valuable when the time-sensitivity is palpable in trauma interventions [19-30].

This study reviews several strengths aspects of telemedicine such as generally, treatment in a high-risk (population, condition, and location) and removal of barriers to care of traumatic patients.

In this systematic review, the literature searched in important databases for telemedicine in various fields such as trauma injury, war, rural, and military. The text of the articles and abstracts were examined from various aspects, the 21 articles were evaluated for quality, and then 10 papers entered in a systematic review. This manuscript is in the first study in various fields of telemedicine.

We found that the use of telemedicine in trauma injury, rural and the military is very helpful for high-quality trauma care; also the telemedicine and telephone consultations can be were demonstrated reducing the risk of physician-related medicine mistakes. Also, telemedicine can useful, practical, and preferable procedure of location for care military sexual trauma patients with PTSD and help to them for reducing mental pains and increasing readiness. The economic evaluation of telemedicine was demonstrated cost-saving and cost-effective of telemedicine consultations. We also realized the importance and practicable of telemedicine for improving rural trauma care.

Duchesne et al. [31] were reported that the performance of a telemedicine plan decreases trauma transfers to 89%. Many rural EDs have not board-certified physicians in emergency medicine [32] despite, the increasing of traumatic injury and trauma-related mortality in rural populations.

In a study that uses tele-emergency services, they were indicated to improve 95% quality of care by using tele-emergency services [33]. The clinical care is improved by using of telemedicine because access to specialized physicians [33]. in the other study, they found the utilization of expert physicians via telemedicine helped stabilize trauma patients during early care [34]. This study demonstrated a limit of 8% of patients have received care that may survive through using telemedicine consultation [34]. On the other hand, the levels of task-based communication of care services can be increased through telemedicine care [35]. Lucas Van Oeveren et al results were illustrated telemedicine improves care and enhances accessibility to treatment.

MST-related PTSD as one of the subjects for telemedicine was investigated by Gilmore et al. in particular; HBT increases treatment access women and even men with their MST histories which suffering from other physical or mental difficulties.

Although quality of care is fairly suitable in most EDs to children, it may behave rates of poor events, such as medication errors in non-children's hospitals for seriously ill children [36–38], nevertheless, the telemedicine can provide access to pediatric expertise for a decrease of physician mistakes [39].

The telemedicine programs significantly increase the quality of care and reduce mortality in traumatic injuries, also the telemedicine is the importance and practicable for improving rural trauma care. This producer can be a suitable alternative to traditional care, in other words, this method causes access to skilled and experienced physicians in far-off areas, subsequently; telemedicine can decrease the risk of physician-related ED medication errors particularly in a pediatric case. Besides, telemedicine can useful and practical producer for PTSD patients; and home-based telemedicine access for these patients in their home.

CONCLUSIONS

Ultimately, the telemedicine can help patients and health government organizations economically, the telemedicine consultations due to cost-saving and cost-effective. Further studies to evaluate the running of telemedicine need to abating the practical and high-efficiency method, that can be done everywhere and it's free from mistakes and defects.
